1. Introduction

Air affects climate, air quality, and human health. Urban forests (trees and shrubs) in cities and suburbs provide many benefits, including reducing air pollution, improving air quality, and reducing energy consumption. Urban forests also provide many other benefits, including reducing noise, improving aesthetics, and providing habitat for wildlife. Urban forests are an important part of the urban environment and should be managed and protected.

Air pollution removal by urban trees and shrubs in the United States

David J. Nowak^{*}, Daniel E. Crane, Jack C. Stevens

USDA

Abstract

A United States Forest Service report that urban trees and shrubs remove air pollution and improve human health. The report is based on a study of 100 urban forests in the United States. The study found that urban trees and shrubs remove an average of 1.5 tons of air pollution per year. This is equivalent to removing 1.5 tons of lead from the atmosphere. The report also found that urban trees and shrubs improve human health by reducing air pollution and improving aesthetics. The report is a valuable resource for urban forest managers and policymakers.

1. Introduction

Air pollution is a major problem in the United States. It causes many health problems and damages the environment. Urban forests (trees and shrubs) in cities and suburbs provide many benefits, including reducing air pollution, improving air quality, and reducing energy consumption. Urban forests also provide many other benefits, including reducing noise, improving aesthetics, and providing habitat for wildlife. Urban forests are an important part of the urban environment and should be managed and protected.

What about Near-Road Air Quality?

Elevated pollutant concentrations have been measured near roads:

- NAAQS (CO, NO₂, PM₁₀, PM_{2.5})
- Particulate Matter constituents (e.g. ultrafine particles, black carbon, metals)
- Air Toxics (e.g. benzene, polycyclic aromatic hydrocarbons)

Living, working, or going to school near major roadways has been associated with numerous adverse health issues:

- Increased risk of adverse respiratory, cardiovascular, birth, cancer, and mortality effects
- International consensus on “public health concern”

A significant portion of U.S. pop. lives near large roads:

- 2007 American Housing Survey estimates >45 million people live within 100m of a major transportation facility, the majority of which are large roads.
- ~2 million children go to school near large roads; many also work in these areas.
- These residences and schools are disproportionately lower income.

Modeling Solid-Wall Barrier Effects

Computational Fluid Dynamics:

No barrier

6m barrier

18m barrier

Hagler et al. 2011. *Atmospheric Environment*.

Presence of solid-wall barrier dramatically alters the dispersion of roadway emissions, leading to more vertical lofting of the plume and reducing ground-level concentrations behind the barrier. (On-road concentrations are modeled to increase with a barrier present.)

Wind Tunnel Simulations:

Needle and Broad-Leaf Evergreens

Findings:

Moderate reductions in ultrafine particles

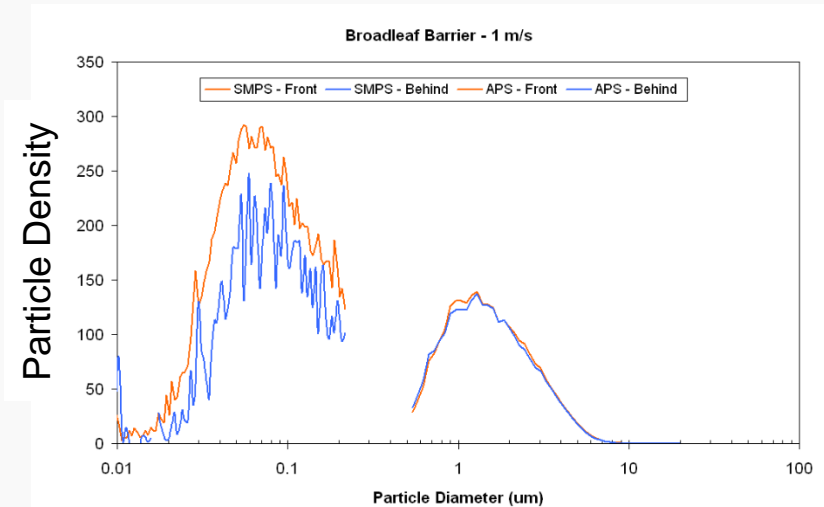

Larger particles unaffected

Effects on Black Carbon ultrafines (diesel indicator)

Detroit, MI Field Site
(continuous sampling for 28 days)

Brantley et al. 2014. Science of the Total Environment.

Research Impacts to date

EPA is incorporating roadside vegetation effects into research and voluntary recommendations:

- ✓ **Siting guidance for implementing the national near-road monitoring network**
- ✓ **Air quality modeling applications**
- ✓ **School siting and design guidelines for potential exposure mitigation**

Other federal, state & local organizations are exploring roadside vegetation for mitigating near-road air quality impacts:

- ✓ **USDA Forest Service – *i-Tree* module**
- ✓ **Transportation Research Board**
- ✓ **California Air Resources Board**
- ✓ **School pilot in Atlanta**

Planned Research Synthesis may incorporate Eco-Epidemiology

NOx

Annual Average Concentrations ($\mu\text{g}/\text{m}^3$)
by Census Block-Group

Take-Home Messages

- **Models and fieldwork suggest that vegetation has the potential to improve near-road air quality.**
- **Research to date shows promise for ultrafines in particular.**
- **Results vary depending on wind speed, direction, seasonality, road design, and traffic conditions.**
- **Barrier type and configuration are critical (e.g., species, depth, gaps, and edge effects).**
