# Future Climate Scenario

Global climate change and regional freshwater ecosystem models (IPCC) agree on three key findings;

1. water temperatures will increase 2 to 3°C and,
2. the frequency of high intensity rainfalls and large flood events will increase,
3. decreased duration of flooded/saturated conditions due to lower baseflow and higher ET

# Study Questions

1. How do species-richness, diversity, and “degree of invasion” differ under varying pulsed water and temperature regimes?
2. How have interactions between hydrology and temperature affected the current community composition/invasibility of southeastern floodplain ecosystems at the regional scale?

# Methods

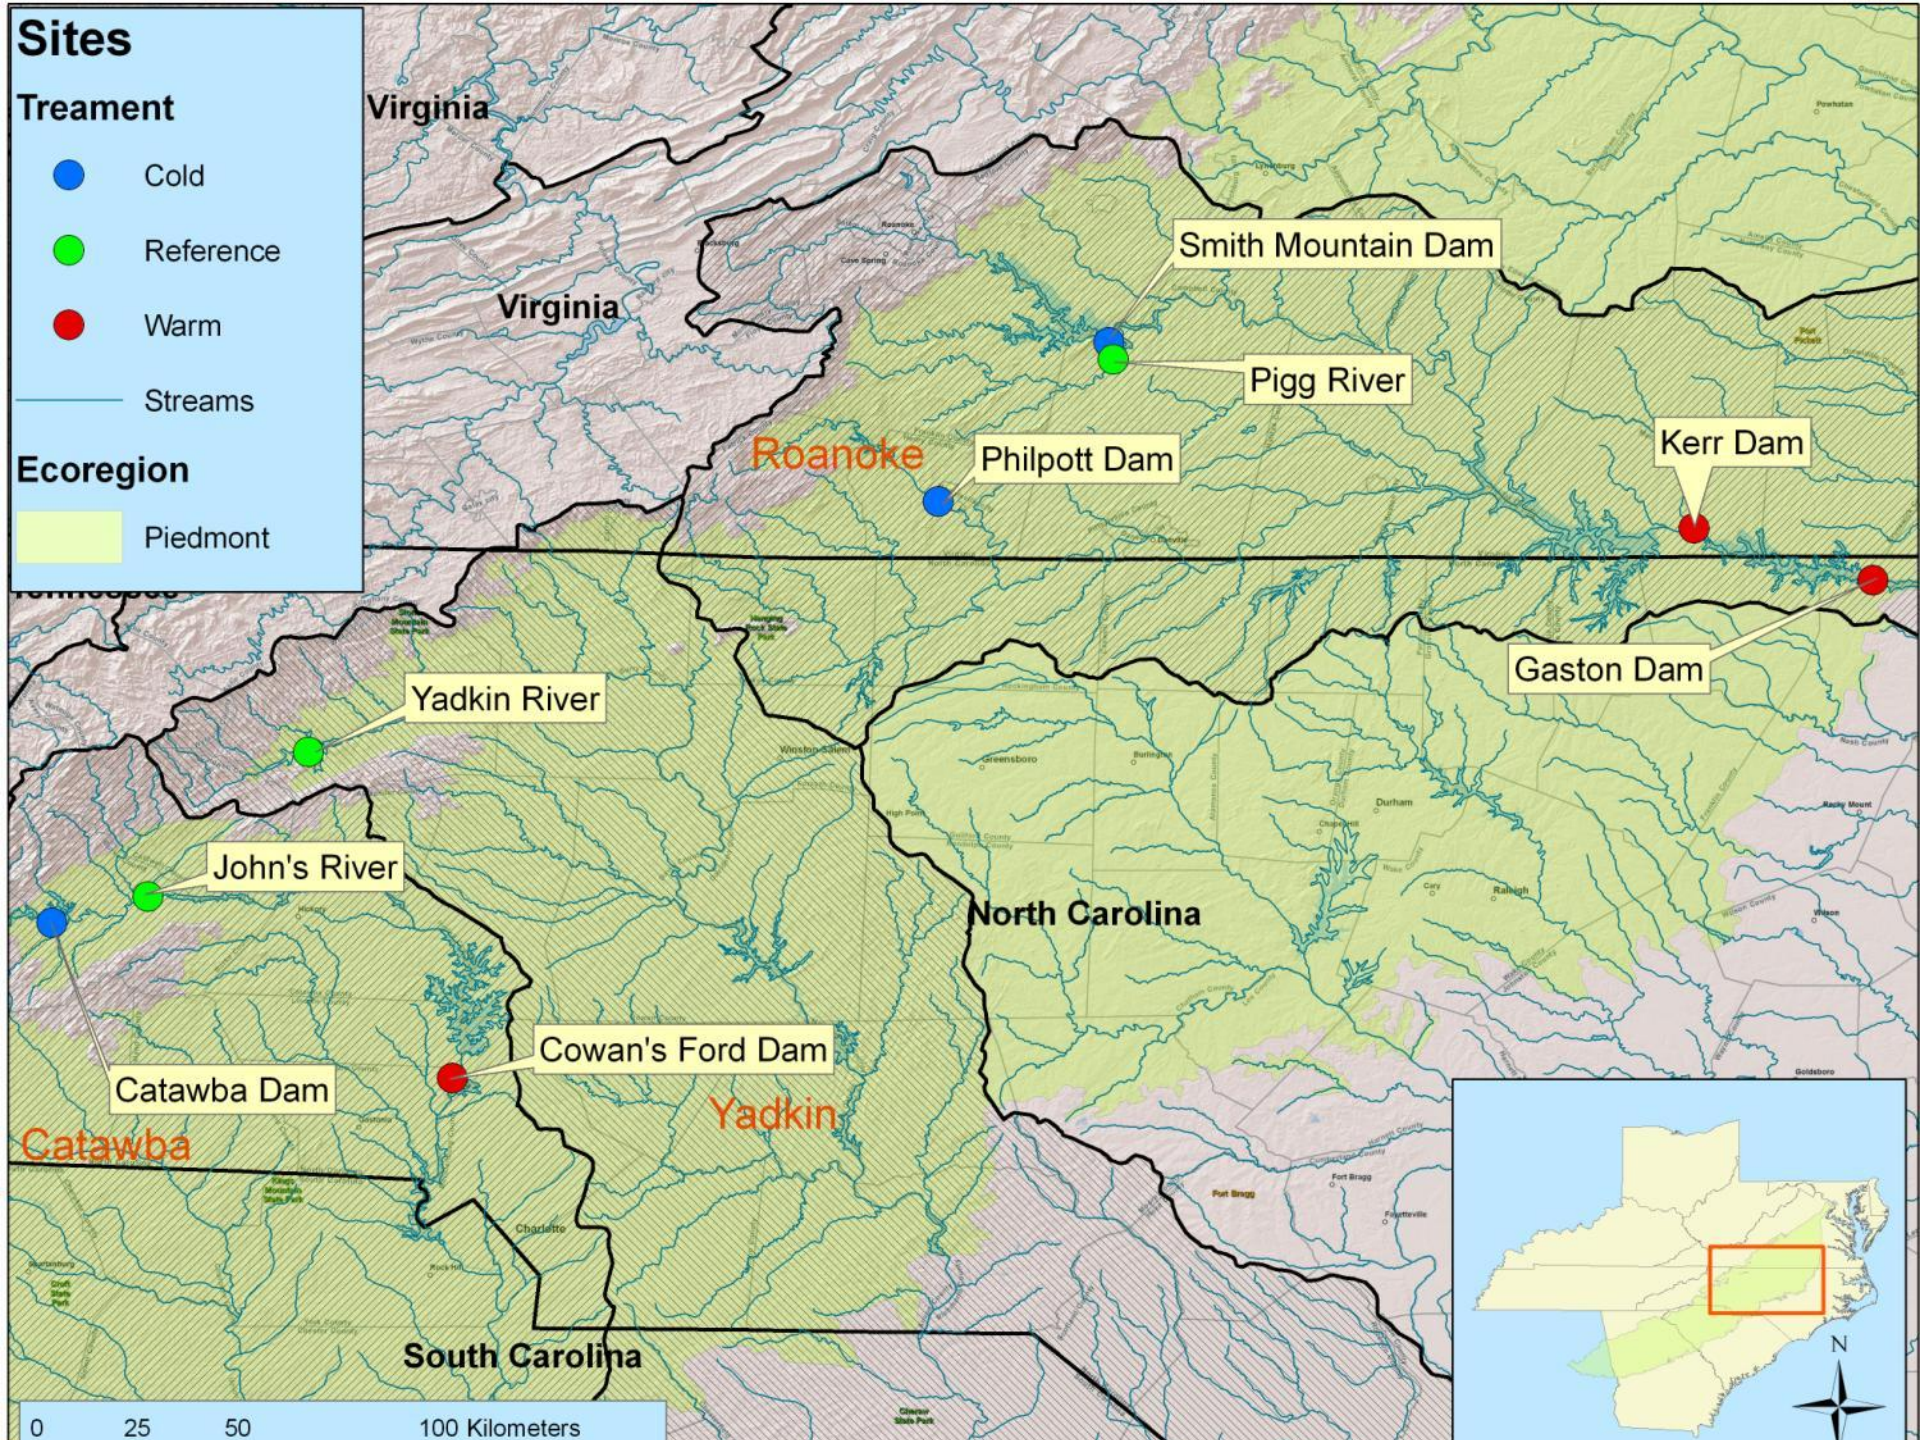

# Site Layout

- Nine floodplains wetlands located on rivers throughout the North Carolina and southern Virginia.
- Downstream of:
  - 3 surface drawing dams (warm water)
  - 3 bottom-releasing dams (cool water)
  - 3 undammed reference watersheds

# Site Selection Criteria

- Located within the Piedmont Ecoregion
- Headwaters in mountains
- Primarily rural (forest and agriculture)
- Similar soil/water nutrient regimes

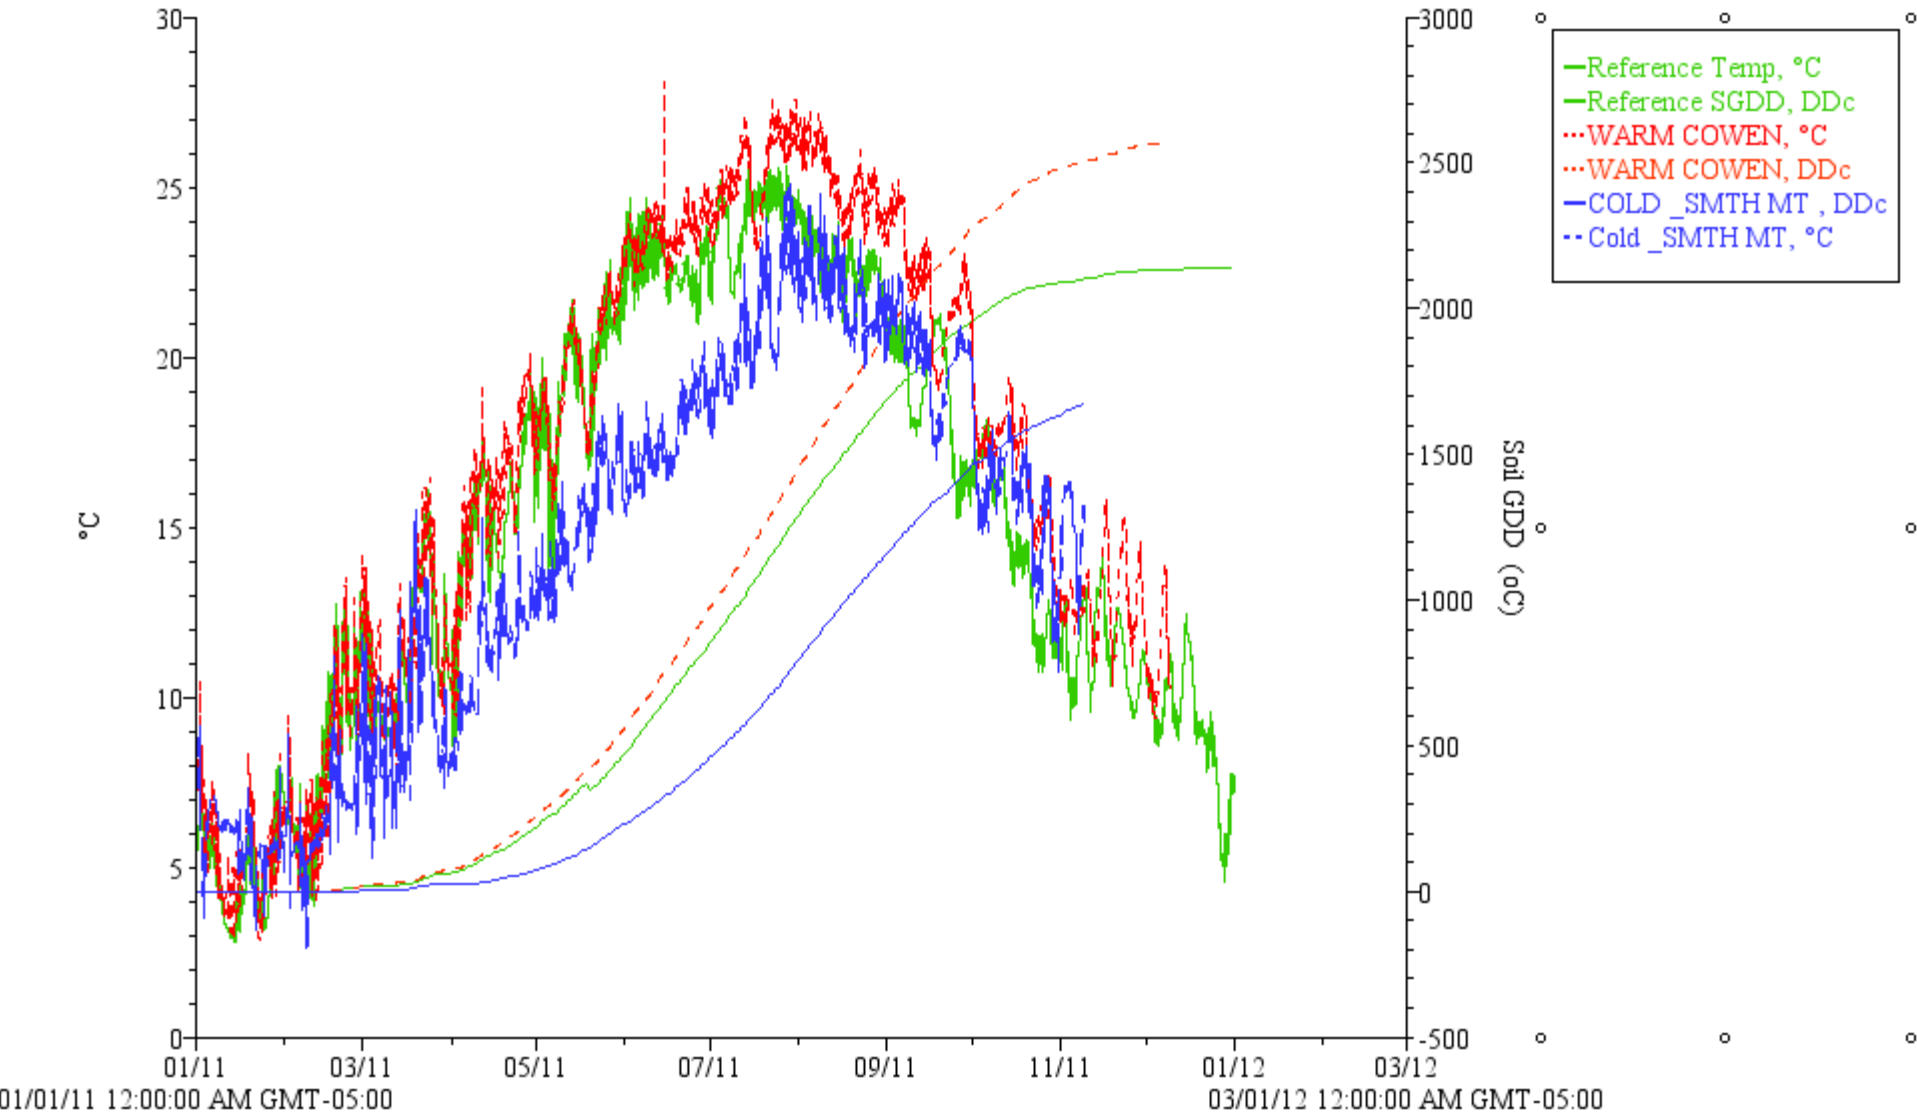

# Site Layout

# RESULTS

# Representative SGDD Curves

# Hydrology Numerical Summary

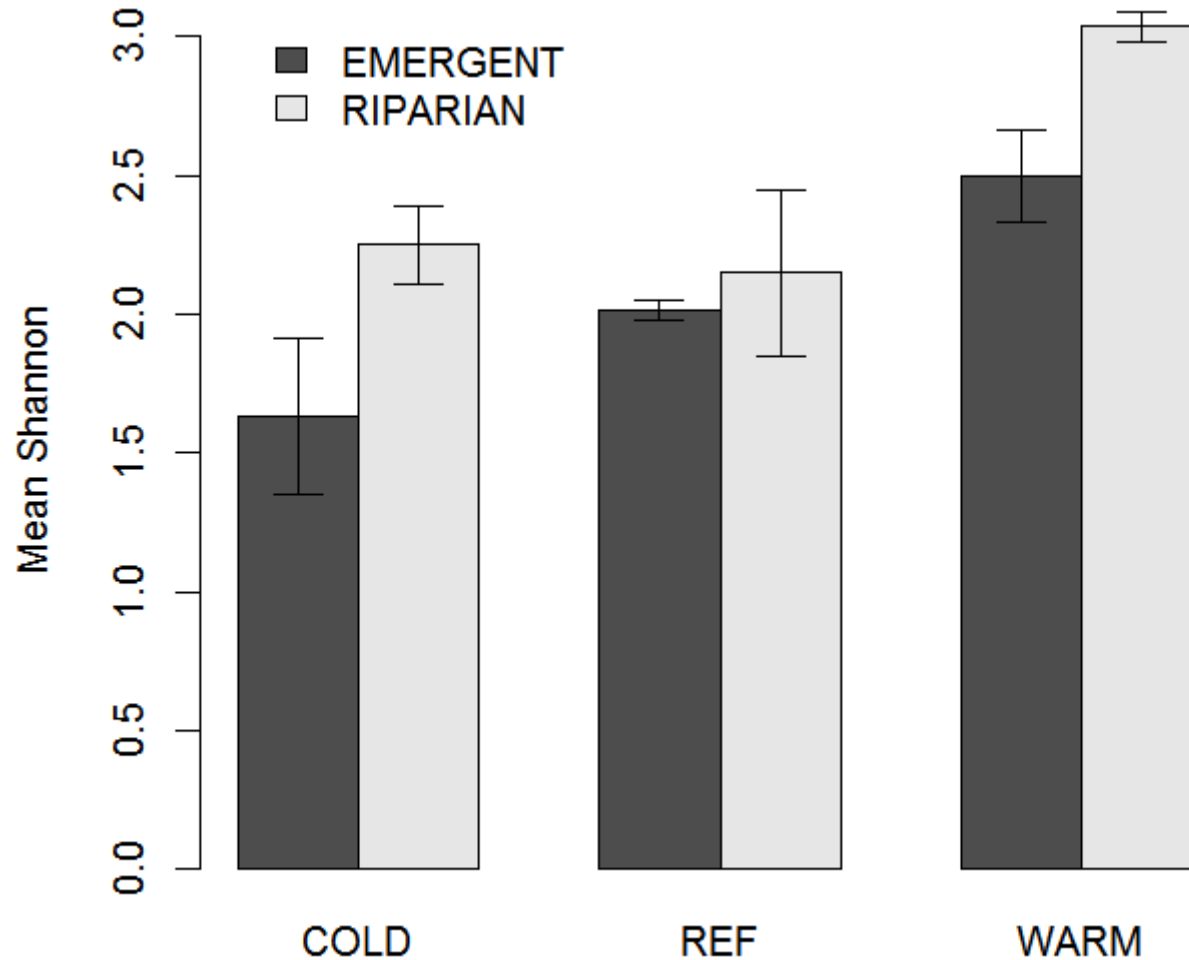

<b>Treatment</b>	<b>Flood Frequency</b>	<b>Average Flood Duration (hrs)</b>	<b>Total Inund. Duration (hrs)</b>	<b>Average Return Period (hrs)</b>	<b>MEAN Rate Rise "POWER" (mm/hr)</b>
Warm	432	4.26	1842	38.7	121
Reference	306	10.7	3291	90	84
Cold	485	4.3	2099	34.4	173

# Analysis of Plant Community Indices

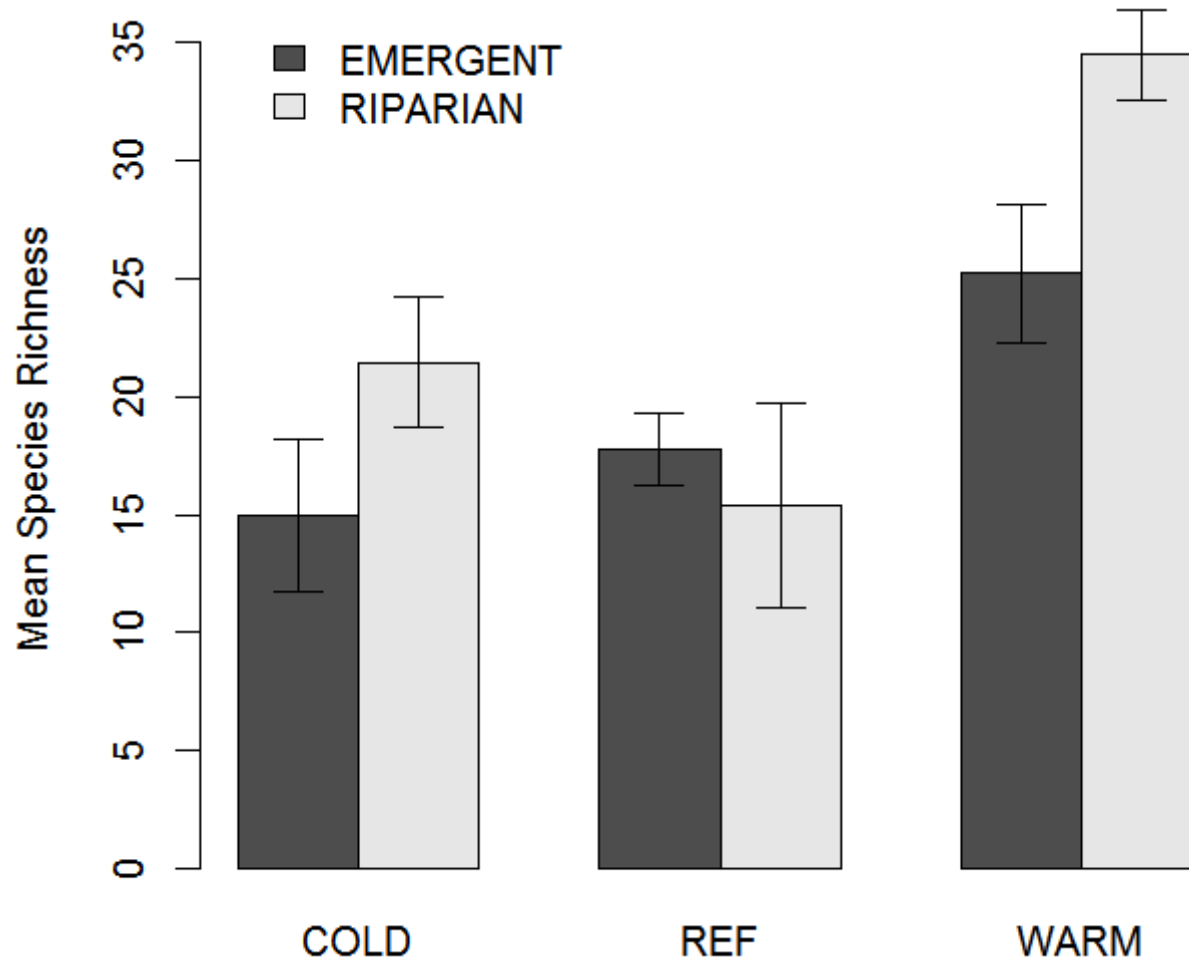

- Site specific indices of diversity, species richness, degree-of-invasion, dominance

[2486.2008.01824.x/full#f1](http://onlinelibrary.wiley.com/doi/10.1111/j.1365-2486.2008.01824.x/full#f1)

# Summary

- ↑ Temperature scenario associated with;
  - ↑ diversity, species richness
  - ↓ degree of invasion
  - ↓ Invasive biomass
- ↑ Flooding associated with;
  - ↓ diversity (Power, Duration)
  - ↑ degree invasion (Number Floods)
- Outcome of climate change will depend on tradeoff of hydrology , temperature, and movement of invasive propagules

# Conclusions

- Temperature and hydrology were significant predictors of invasive species
  - Cold sites- create bioclimatic envelopes that favor temperate invaders from cooler headwater (mountain) climates
  - Warm Sites-increased temperature could also create envelopes for warm climate invaders from coastal plains,
    - inhibited upstream invasive propagule movement may reduce envelope utilization
  - Increased flood power may disturb native communities making them more vulnerable to invasion, and aid in invasive propagule distribution

# GRADIENT SITES

Three sites with similar

- Soils,
- Hydrology
- Propagule source
- Temperature gradient toward ambient with movement away from dam

# SGDD – Gradient Sites
