

Development of Sampling Protocols for the Surface Elevation Table

James C. Lynch – National Park Service

Donald R. Cahoon – U.S. Geological Survey

Philippe Hensel – N.O.A.A., Geodetic Survey

- The SET is unique in that it ties the changes in marsh elevation to a stable reference mark (the deep Rod or Pipe).
- Hard to find stable reference marks in wetland environments.
- This is one of the first methodologies to accurately monitor relative elevation change over time in wetlands.

The SET provides important data needed for assessing tidal marsh health:

Tidal Marshes

1. Elevation of the marsh surface (surveying)
2. Rate of change - marsh surface (SET)
3. Elevation of the adjacent water body (NOAA)
4. Rate of change - adjacent water body (NOAA - SLR)

SET has been in use for over 20 years

The Surface Elevation Table: History

Original Design: Used for about 10-15 years
(1989 - early 2000's)

- First used in Louisiana by LSU graduate student Roel Boumans.
- SET design – large and somewhat heavy
- Installation — 15-25 feet deep benchmark. Stable?

Original SET : Big!

Original SET : Benchmark Installation

Major Points:

- 1) Somewhat difficult to install.
- 2) Benchmark was not very deep - <25 feet (8 meters)

SET Today:

multiple instrument designs

“SUPER” ROD SET – SERC, MD – P. Megonigal design

SET Today – Benchmark Installation

The Surface Elevation Table:

Today:

- Used in 25 U.S. States – mainly on the coast.
- Used in 25 Countries – possibly two in Africa (?).
- Multiple improved designs of the instrument.
- Multiple installation options – benchmarks are much deeper than original design. There is also a Shallow benchmark option (4 legged platform).
- Used in all types of wetland environments - mangroves, salt marshes, brackish marshes, freshwater marshes.
- All types of users.

The SET has become a standard tool used to monitor elevation change in wetlands.

SET Protocol:

The National Park Service in collaboration with colleagues in the USGS and NOAA are writing this protocol to provide detailed guidelines on the installation and use of SET's in wetland environments.

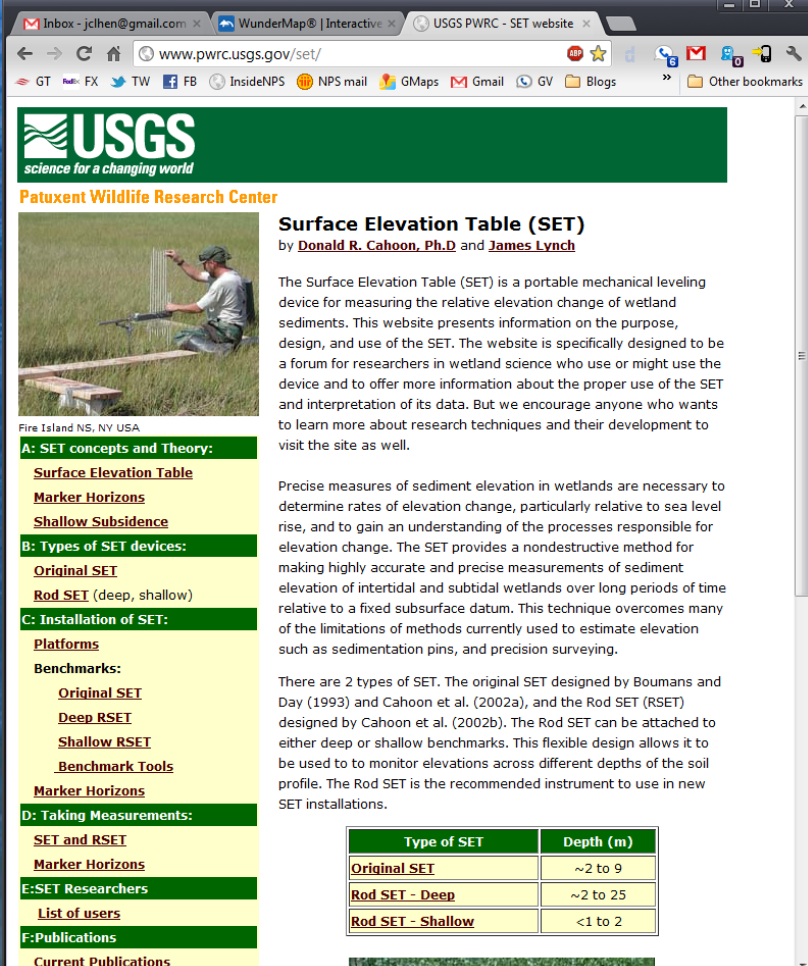

This document is being published by the National Park Service but is intended for use by all groups interested in using the SET for research and monitoring.

SET Protocol:

Major topics covered in this document are:

- A. SET study design
- B. Installation & sampling
- C. Data processing -

Surface Elevation Table (SET)

by [Donald R. Cahoon, Ph.D](#) and [James Lynch](#)

The Surface Elevation Table (SET) is a portable mechanical leveling device for measuring the relative elevation change of wetland sediments. This website presents information on the purpose, design, and use of the SET. The website is specifically designed to be a forum for researchers in wetland science who use or might use the device and to offer more information about the proper use of the SET and interpretation of its data. But we encourage anyone who wants to learn more about research techniques and their development to visit the site as well.

Precise measures of sediment elevation in wetlands are necessary to determine rates of elevation change, particularly relative to sea level rise, and to gain an understanding of the processes responsible for elevation change. The SET provides a nondestructive method for making highly accurate and precise measurements of sediment elevation of intertidal and subtidal wetlands over long periods of time relative to a fixed subsurface datum. This technique overcomes many of the limitations of methods currently used to estimate elevation such as sedimentation pins, and precision surveying.

There are 2 types of SET. The original SET designed by Boumans and Day (1993) and Cahoon et al. (2002a), and the Rod SET (RSET) designed by Cahoon et al. (2002b). The Rod SET can be attached to either deep or shallow benchmarks. This flexible design allows it to be used to monitor elevations across different depths of the soil profile. The Rod SET is the recommended instrument to use in new SET installations.

Type of SET	Depth (m)
Original SET	~2 to 9
Rod SET - Deep	~2 to 25
Rod SET - Shallow	<1 to 2

SET website:
www.pwrc.usgs.gov/set/

A) Study Design.

This section will address some commonly asked questions about SET installations;

- A. Where do I put my SET's? – Random location
- B. How many SET's do I install? - Sample Size
- C. How often do I sample? - Sampling frequency
- D. Do I measure Accretion? Is it required?

Sampling Design:

Monitoring and Hypothesis testing:

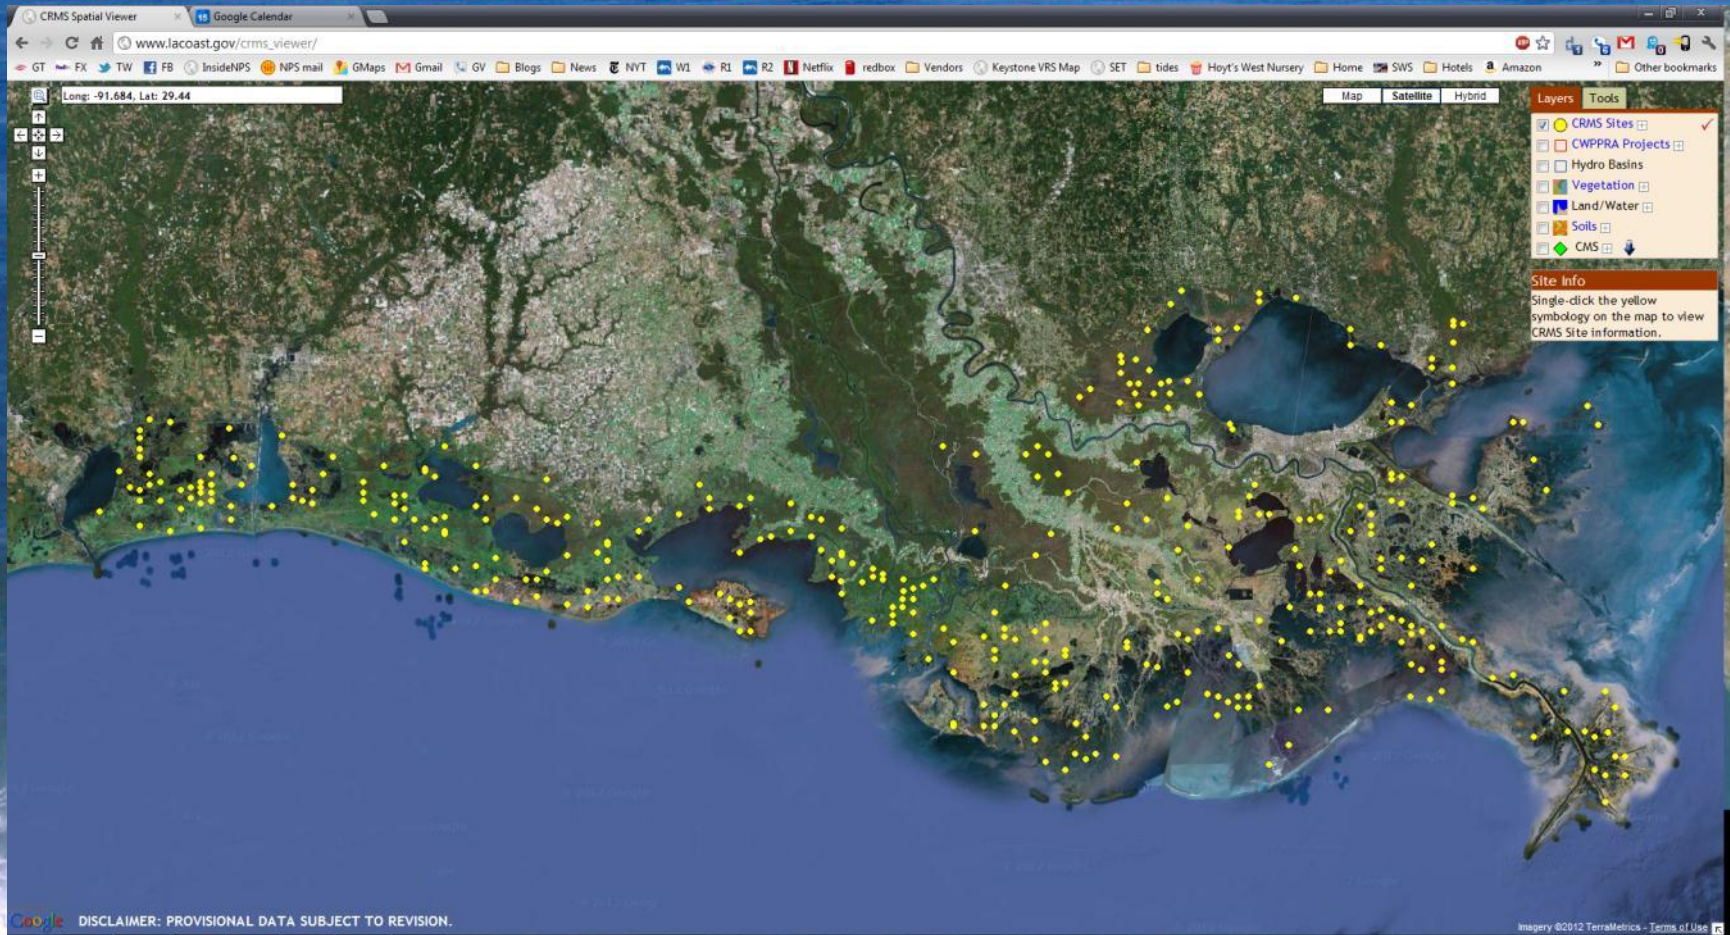

1. General considerations
2. Sampling for monitoring
 1. Representative vs. random sampling
 2. Restricted randomization and controlling variables
 3. Monitoring examples
3. Sampling for hypothesis testing
 1. Statistical Power
 2. Experimental unit
 3. Statistical sampling theory
 4. Representation and independence
 5. Distributional requirements
 6. Statistical models & their influence on sampling design
 7. Hypothesis testing examples

Many groups are using the SET for monitoring.

- USFWS - Incorporating the SET into many coastal refuges
- NPS - Incorporating the SET into coastal parks in NE and SE regions of the US
- NOAA - SET is part of the National Estuarine Research Reserve (NERR) monitoring program
- Louisiana - is using the SET as part of a large scale monitoring program.

Louisiana – Coast-wide Reference Monitoring System

390 monitoring sites

Assateague Island National Seashore
Berlin, Maryland USA.

16 SET's – Where to put them?

- a) Randomly across the entire site?
- b) Randomly located with randomly located marsh units?

Constraints:

Horses

Marsh Type

Proximity to Bay

Logistics – site access

Etc....

We're not advocating one design over the other in this example. The point is that there are a lot of issues that have to be considered when choosing SET sites.

B) Installation and Sampling:

- How much does an SET installation cost?
- How do I install the deep benchmarks?
- How often do I make measurements?
- Who takes the measurements?
- Accretion plots – installation/sampling.
- Surveying options

B) Installation and Sampling:

SOP # 1 – Project Planning [Checklist or flow chart]

Installation:

SOP # 2 – Choosing SET site location

SOP # 3 – Establishing sampling plots and platforms

SOP # 4 – SET benchmark Installation (& datasheet)

SOP # 5 – Establishing Marker Horizons

SET and marker horizon sampling:

SOP # 6 – Sampling SET plots – Datasheets

SOP # 7 – Sampling Marker Horizons plots

SOP # 8 – Safety

Surveying:

SOP # 9 – GPS elevation surveying of SET sites

SOP # 10 – Leveling the SET's – stability of SET marks

C) Data processing:

Sampling Events

SET Protocol Document – draft text finished by later this year.

Please note that the protocol is only a guideline! End users will ultimately have to determine the design of their particular study based on the constraints that exist for their particular site.

Issues with the randomly locating SET's

Sample Design	Financial Constraints	Logistical Constraints	Prior Knowledge of Site	Spatial Coverage / Inference	Analysis	Data Outcome	Example
Single SET in sample space A (analogous to a tide gauge)	Low	Low	High	Low / Minimal	Regression: single point over time	Single point trend; low site-specific knowledge; No variance estimate for space A; no variance estimate for sites	Theoretical; depends on definition of sample space
Multiple SETs randomly distributed over sample space A	High	High	Low	High / High	Regression; ANCOVA w/ spatial & other covariates	High spatial coverage; low site-specific knowledge; best variance estimate for space A; no site variance	CRMS, soon Texas Coastal Monitoring
Multiple sites randomly distributed over sample space A; SETs randomly distributed within each sample site (e.g. 1)	High	Moderate	Moderate	Moderate / Moderate	Regression ANOVA ANCOVA w/ covariates	Moderate spatial coverage; high site-specific knowledge; some variance estimate for space A; best estimate of variance for sites	Assateague, Fire Island, others
