Wetland risk assessment Great Barrier Reef catchments

- ~2000 km coral reef and coastline
- GBR catchments 424 000 km² (163,706 m²)
- ~274,435 ha natural wetlands >1 ha
- Human impacts
- Reef Plan wetland target - 2013
- Wetland loss 25% , 850 ha 2001-05

The first comprehensive & systematic spatial assessment of risk to wetlands in Queensland to prioritise:

- management: to target management resources
- monitoring: to target monitoring resources

dry phase

dry phase

wet phase

15 MAY 2010

67° ENE mag
E: 149° 06' 12.14"
S: 027° 04' 49.11"

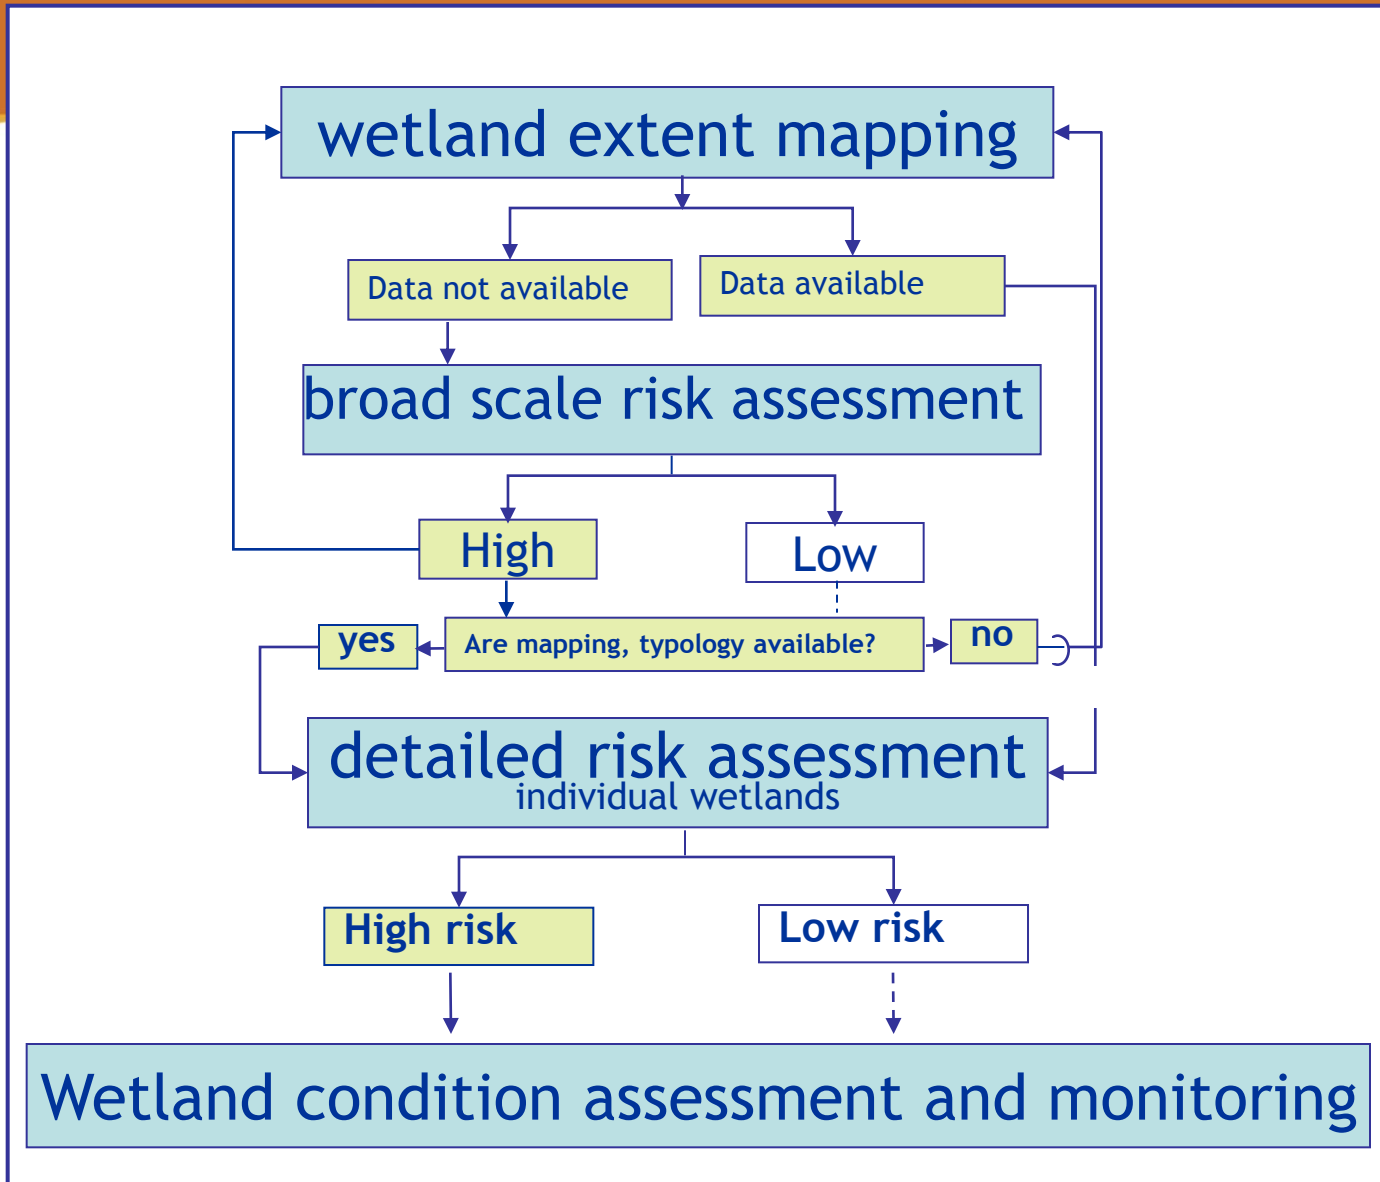

wet phase

12 MAY 2010

188° S mag
E: 150° 00' 56.46"
S: 028° 20' 48.91"

Towards a Queensland wetland monitoring program

Foundational tools and resources

Wetland mapping

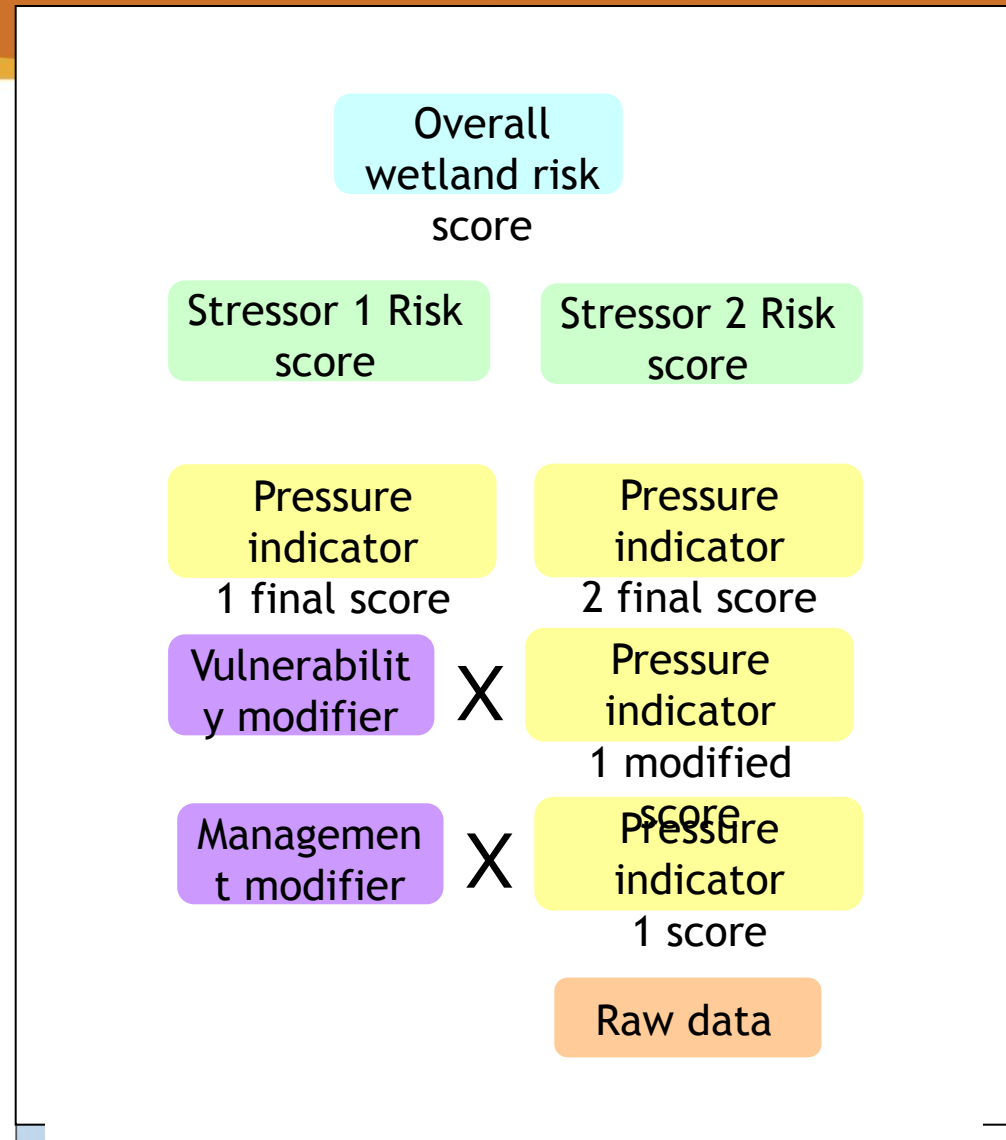

Risk / condition framework

Stressor models

Pressure indicators

GIS/ spatial methods

Assessment software

The GBR wetland risk assessment

Risk assessment based on:

- **individual wetlands at the local level**
- **application of data for 17 broad pressure indicators/measures**

Steps:

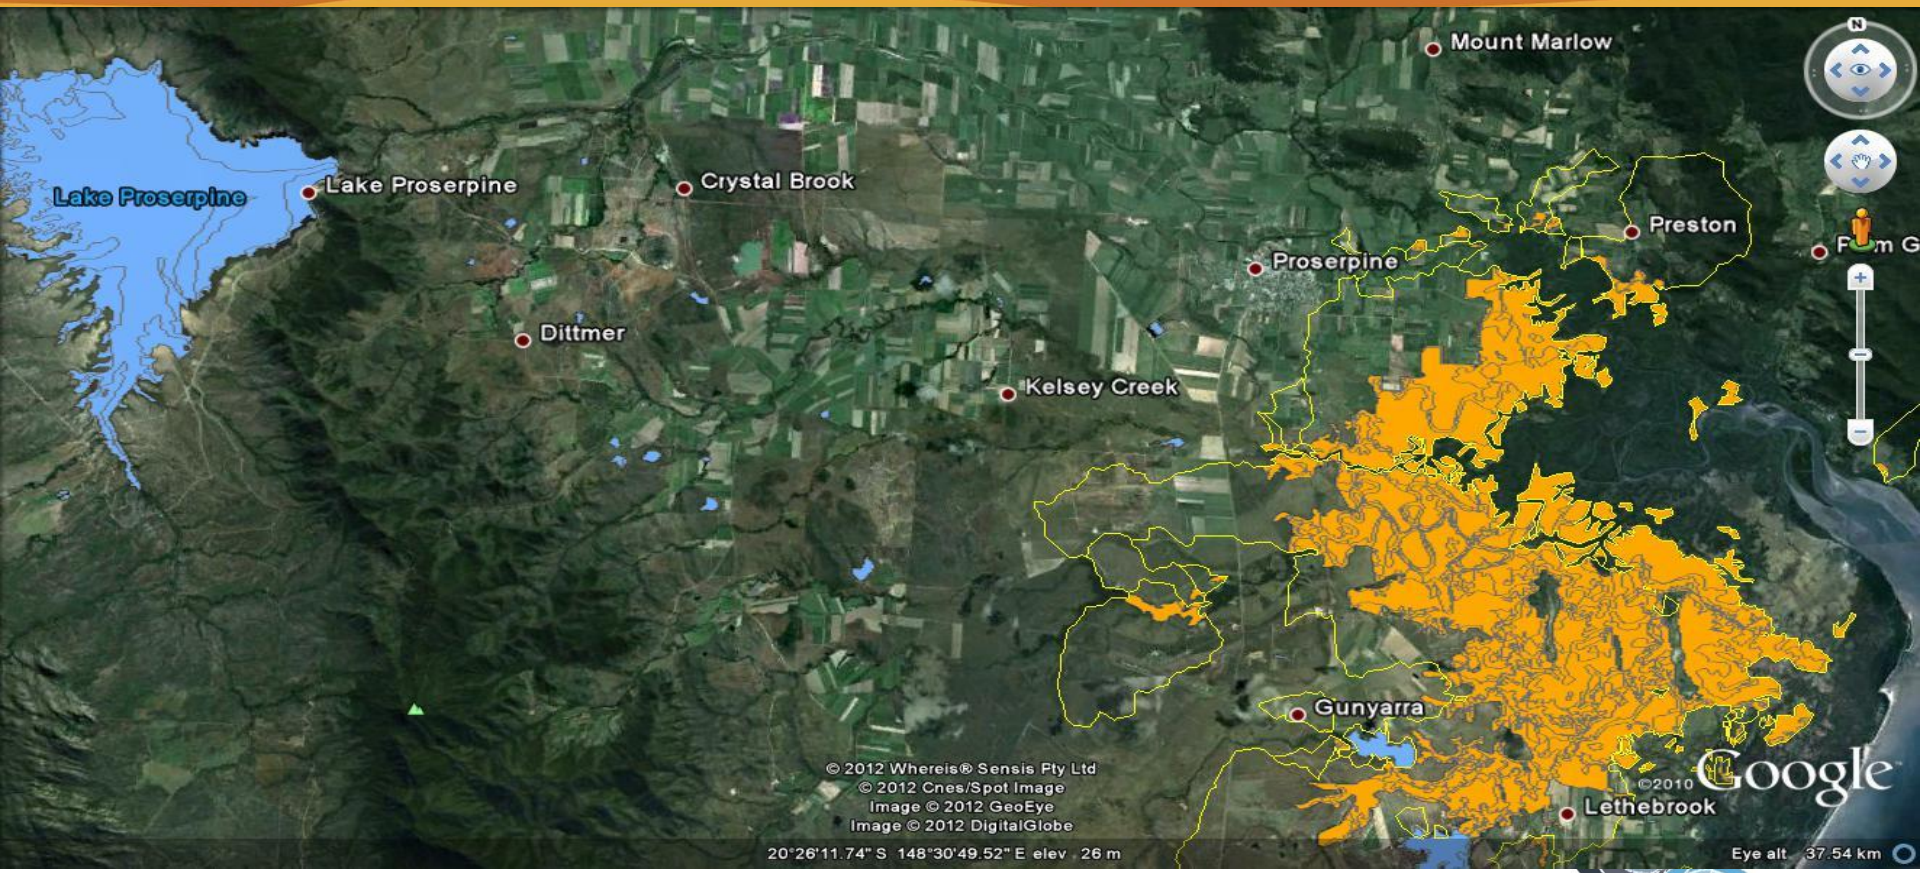

1. **Local watershed delineation based on mapping & DEM models**
2. **Spatial application and review of pressure indicators**
3. **Review stressor framework and models for national alignment**
4. **Consultation and engagement at each stage**

Brick wall!

Adaptive management.....

Capturing pressures from local to landscape

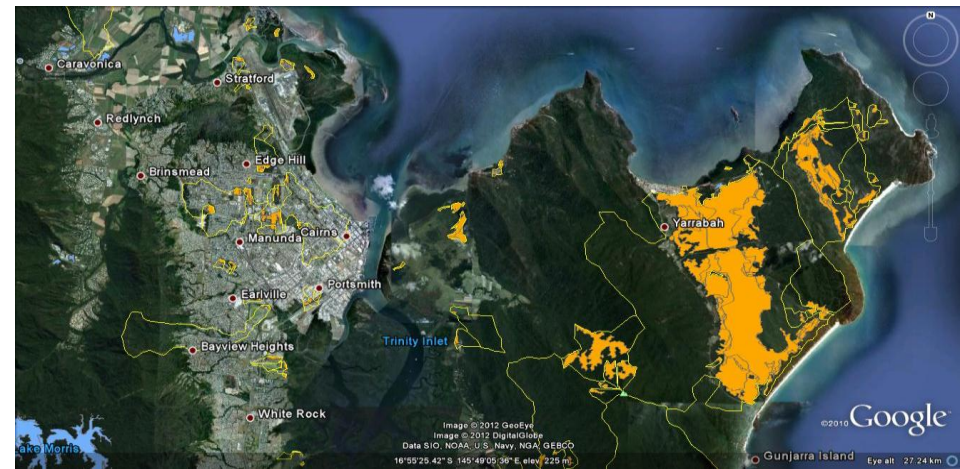

Practical and conceptual challenges

Watershed delineation challenges

- Hydrological focus
- Coastal complexity
- Hydro-geo-physical relations
- Connectivity processes
- Best for isolated depressional wetlands

Stakeholders

- broad strategic v local
- watersheds for dry season

PSR framework and indicator review

Pressure, stressor, response (impact)

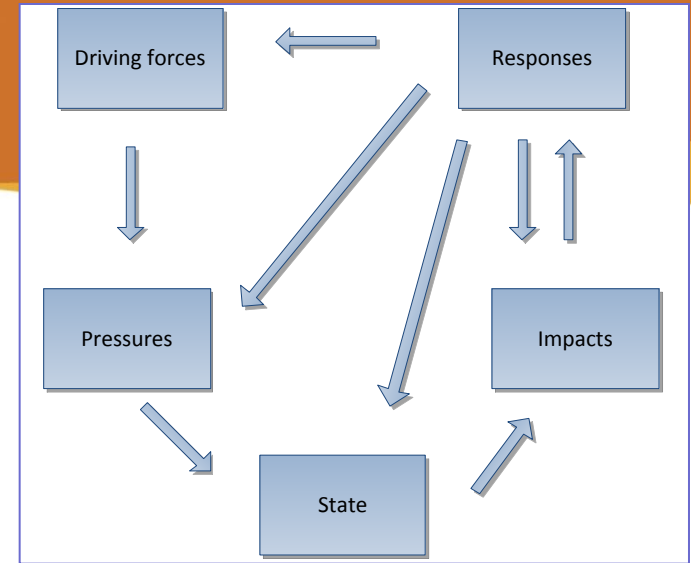

- A PSR model is useful when investigating ecological causal relationships. Each stressor and web of relationships is individually considered.
- Stressors are often confused with pressures and challenging to wetland managers.
- PSR does not consider underlying socio-economic factors or such as drivers or management responses.
- PSR does not provide logical starting and ending points or feedback loops to determine relevant pressures and management response.

DPSIR

European Environment Agency / adopted by the Millennium Assessment

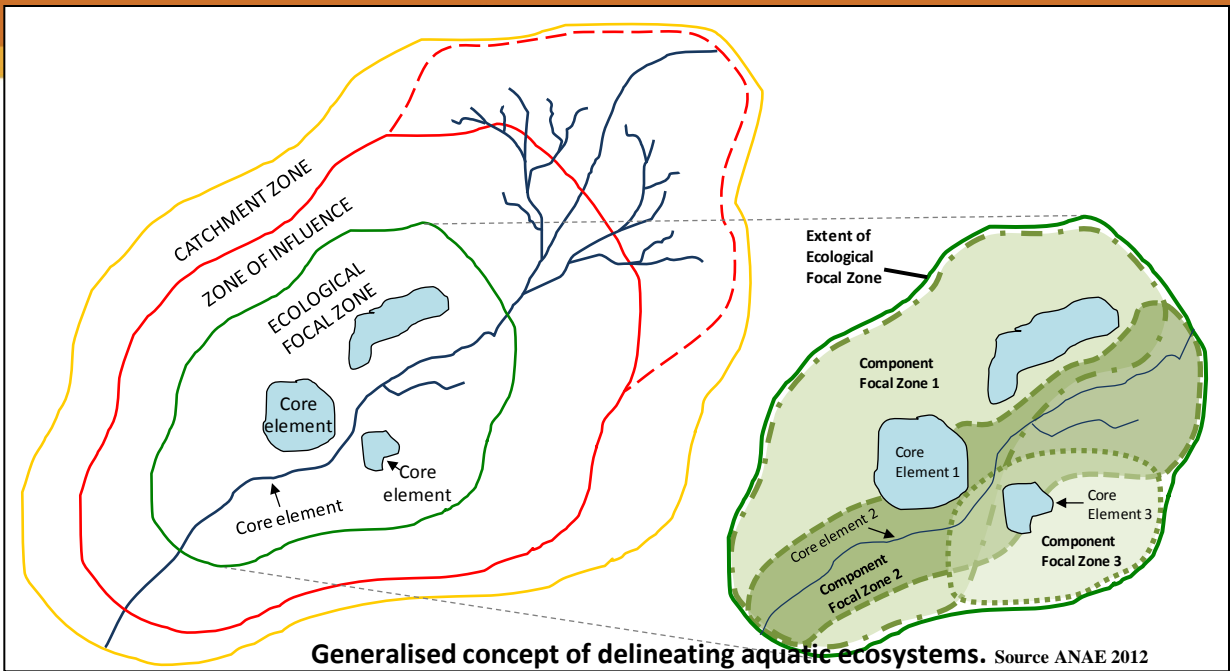

DPSIR describes the interactions between society and the environment

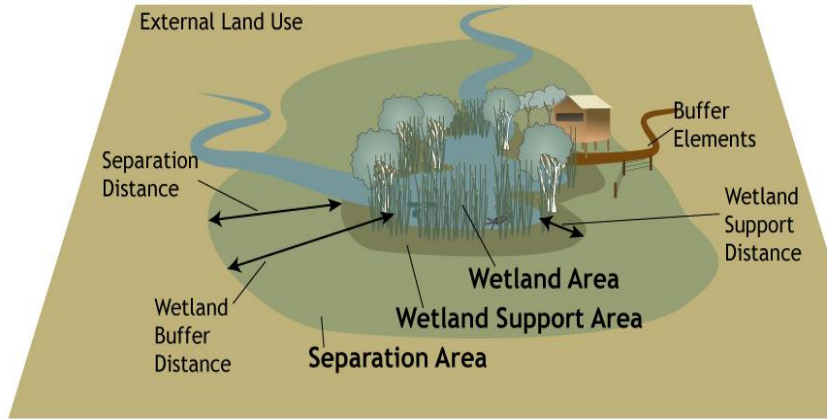

- Provides for assessment of ecological and socio-economic responses
- Logical sequential loops
- Used for targeted management of most relevant socio-economic factors.
- Limited wetland specific examples in literature
- Inconsistent applications and definitions, challenged by scale
- Land use drivers

Delineations and buffer areas for scale specific indicators

- nested zones
- connections
- local embedded in broader scale

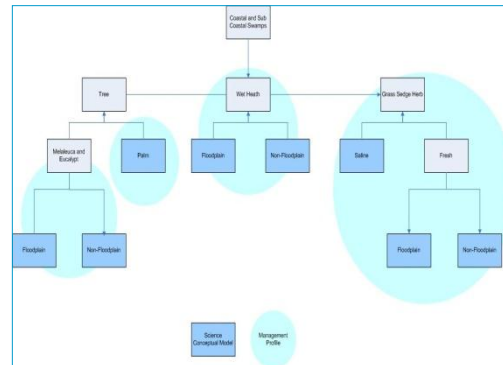

- pressure indicators at scale
- weighted for risk assessment

Wetland types respond differently

- Focus on habitat types
- Adapt DPSIR to consider wetland components & processes
- Develop a regionalisation -future
- Benchmarking types - future

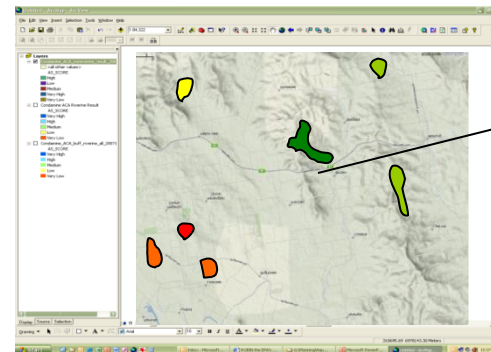

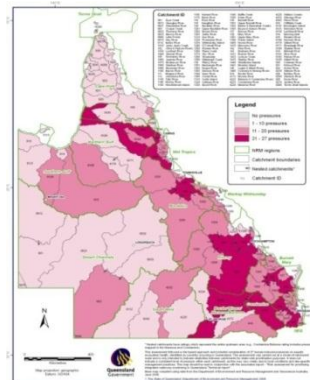

Wetland system
Climate regions
Water type
Water regime
Substrate
Topography
Vegetation

Attribute-based wetland Qld habitat typology

Lessons and conclusions

- DPSIR model is a more comprehensive framework than PSR
- Using land use drivers will provide feedback loops
- Nested delineations are useful for dealing with scale and should be incorporated into risk assessments
- Consideration of wetland types is essential to assess risk
- Be prepared to adaptively manage

Questions & suggestions
