“We would also point out that genetic data is scientific data, i.e., evidence. This is a very different category to economics, social justice, or psychology.”

Table: GRADE's approach to rating quality of evidence (aka confidence in effect estimates)

For each outcome based on a systematic review and across outcomes (lowest quality across the outcomes critical for decision making)

1. Establish initial level of confidence		2. Consider lowering or raising level of confidence		3. Final level of confidence rating
<i>Study design</i>	<i>Initial confidence in an estimate of effect</i>	<i>Reasons for considering lowering or raising confidence</i>		<i>Confidence in an estimate of effect across those considerations</i>
<i>Randomized trials</i> →	High confidence	↓ Lower if	↑ Higher if*	High ⊕⊕⊕⊕
		Risk of Bias	Large effect	
		Inconsistency	Dose response	
		Indirectness	All plausible confounding & bias	Moderate ⊕⊕⊕○
<i>Observational studies</i> →	Low confidence	Imprecision	• would reduce a demonstrated effect or	Low ⊕⊕○○
		Publication bias	• would suggest a spurious effect if no effect was observed	Very low ⊕○○○

*upgrading criteria are usually applicable to observational studies only.

principles for evidence evaluation

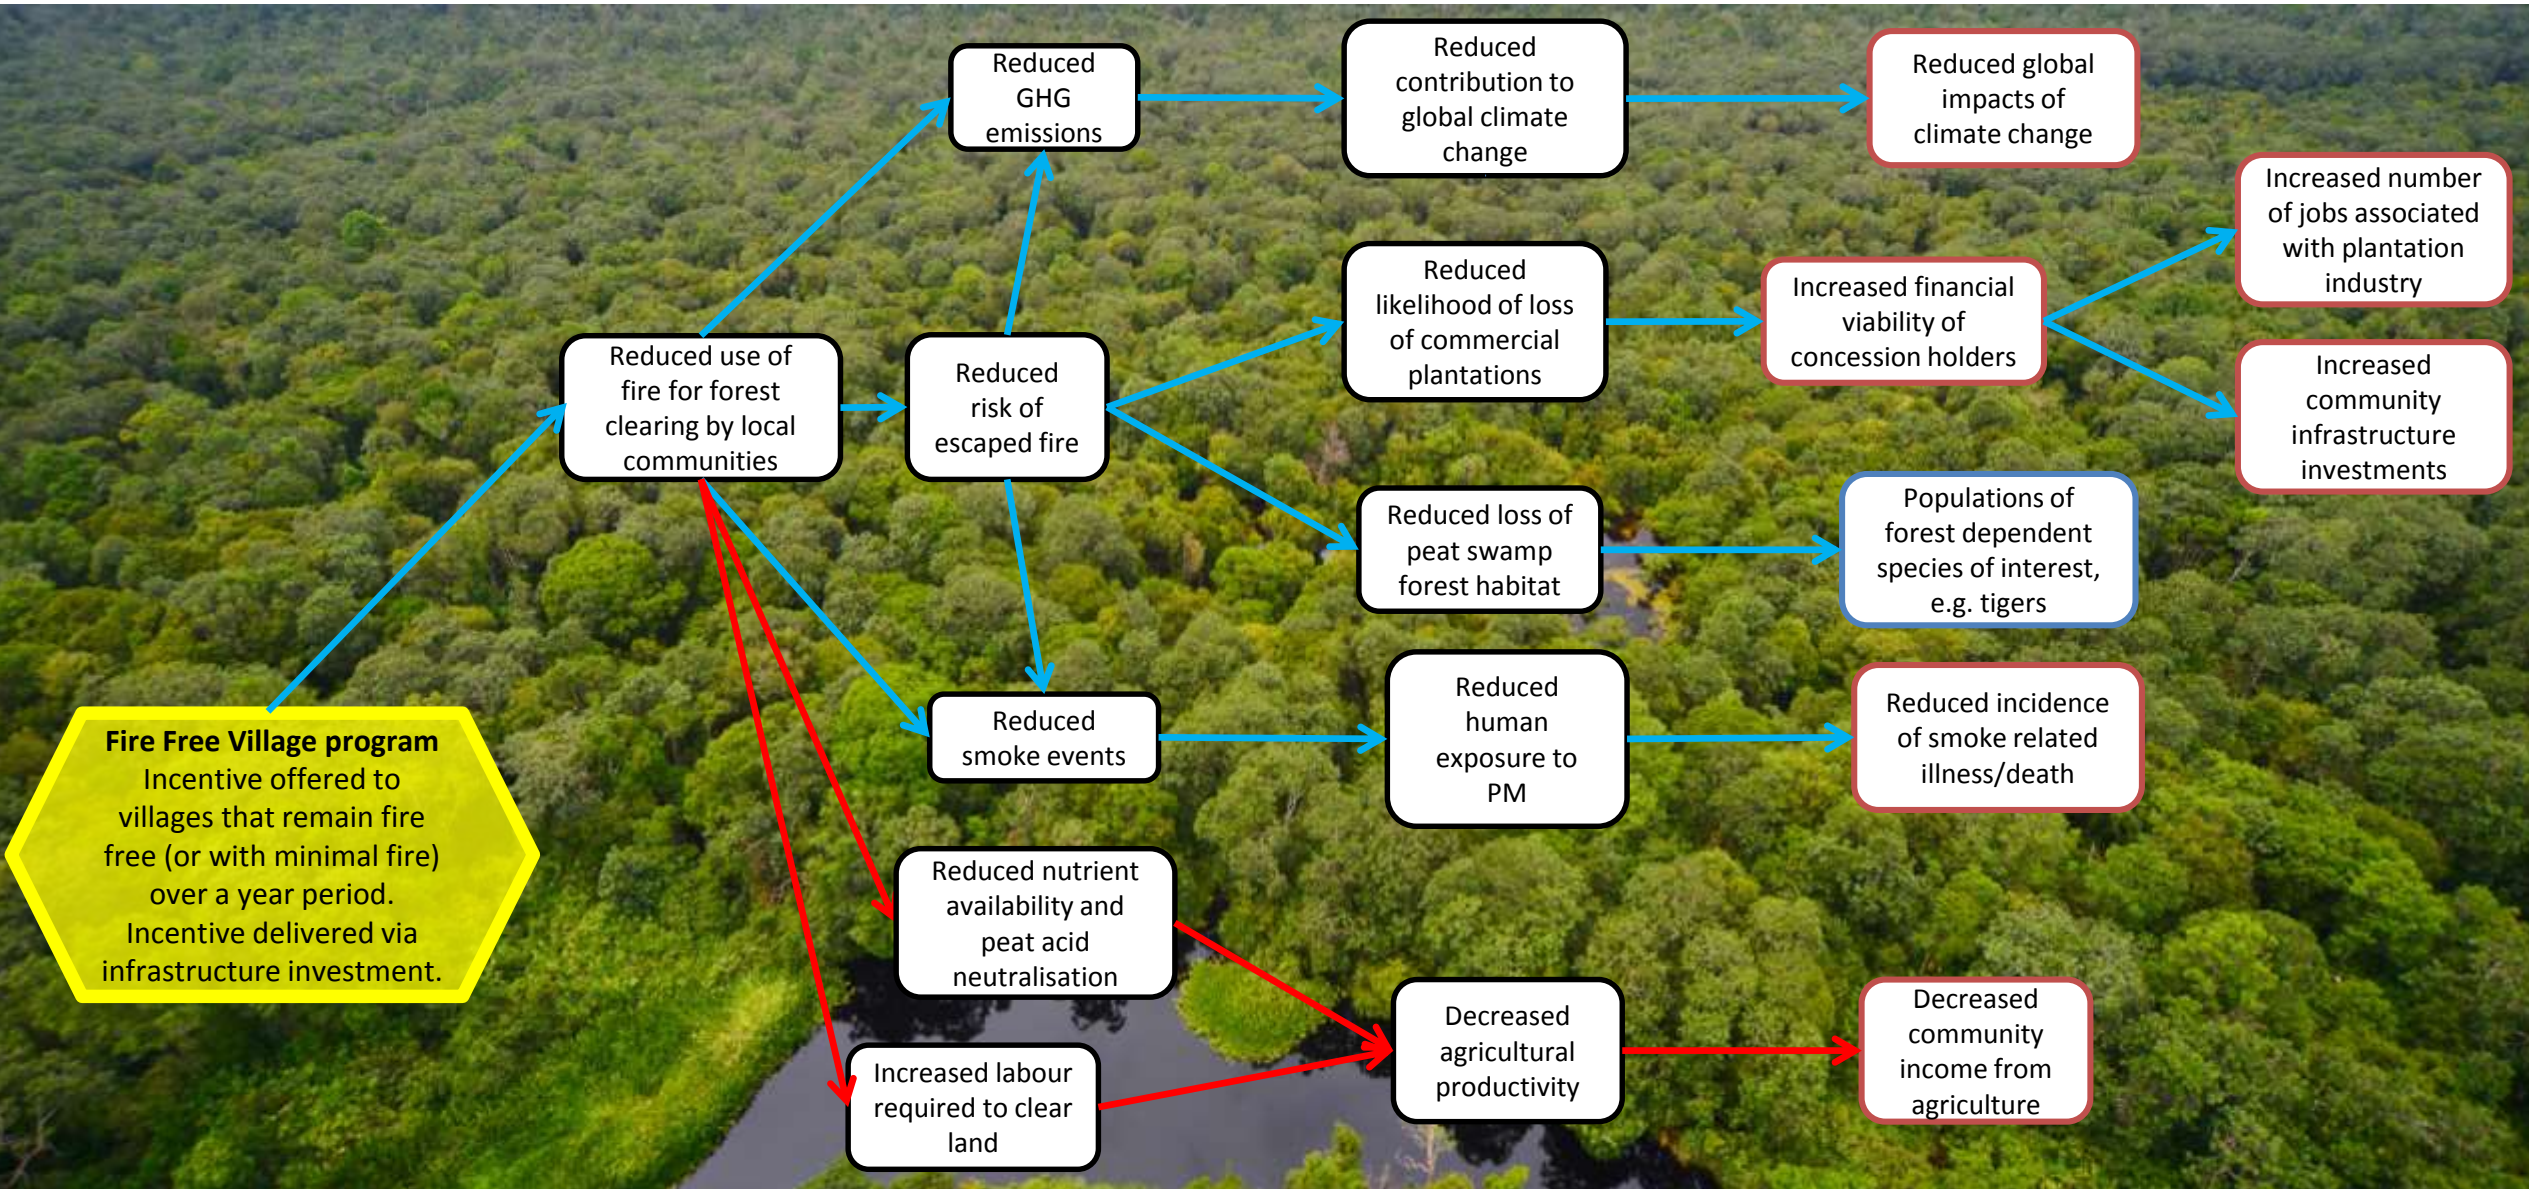

Evidence evaluation should be based on a logic model that identifies **key causal pathways** from intervention to outcomes

For each link, a clear question should be stated, using **PI/ECO** frame (Population, Intervention/Exposure, Control, Outcome)

Information relevant to question should be gathered from **all relevant types**

Key considerations should be applied to the process of evaluating evidence

principles for evidence evaluation

Evidence evaluation should be based on a logic model that identifies **key causal pathways** from intervention to outcomes

For each link, a clear question should be stated, using **PI/ECO** frame (Population, Intervention/Exposure, Control, Outcome)

Information relevant to question should be gathered from **all relevant types**

Key considerations should be applied to the process of evaluating evidence

key evidence considerations

- **Types** of evidence (single or multiple)
- **Consistency** of effect (agreement on sign, size, variance, range)
- **Reliability** (peer review, source/motivational bias, # of studies)
- **Applicability** (how well does the body of evidence fit the question)

ASSESSING COMMUNITY-BASED NATURAL RESOURCE MANAGEMENT
Nature Conservancy scientists created a conceptual model to help assess the efficacy of community-based natural resource management (CBNRM) as a strategy for stemming forest loss and enhancing community well-being in Papua New Guinea (PNG). The conceptual model helped decision-makers to evaluate assumptions and evidence for each activity associated with the strategy and to understand where investment in further evidence was most needed.

(This simplified reproduction includes several examples; the original includes assumptions and evidence for each causal link.)

KEY

	Outcome		Good
	Conservancy activity		Could be better
	Desirable state		Priority to improve
	Undesirable state		Evidence not assessed
