## Dynamics of Metals, Nutrients, Sediments and Carbon in Mediterranean Constructed Wetlands Receiving Agricultural Runoff

C. Ibáñez, N. Caiola, M. Guàrdia, V. Rosales, A. Rovira

IRTA, Aquatic Ecosystems Program, St. Carles de la Ràpita (Catalonia, Spain)

**EBRO ADMICLIM**  
LIFE 13 ENV/ES/001182

# The Ebro Delta is a strongly humanized wetland area

- Around **70% of the delta plain has been converted from wetlands to rice fields** (ca. 20,000 Ha), mostly during the XX century.
- The **hydrology is completely modified by rice cultivation**, leading to a fresher delta with higher river water and nutrient inputs in summer (May-Oct.).
- Dam construction in the lower Ebro river (60's) caused the **retention of 99% of the original sediment load**, leading to coastal erosion.
- Irrigation and other water uses in the river basin have lead to a **reduction of 40% in the river runoff**.
- The remaining **natural wetlands (9,000 Ha) still are a remarkable biodiversity hotspot**, but are small in size, fragmented and affected by hydrological alterations.
- **Constructed wetlands are being built in order to improve water quality from rice field drainage** before reaching shallow coastal waters.

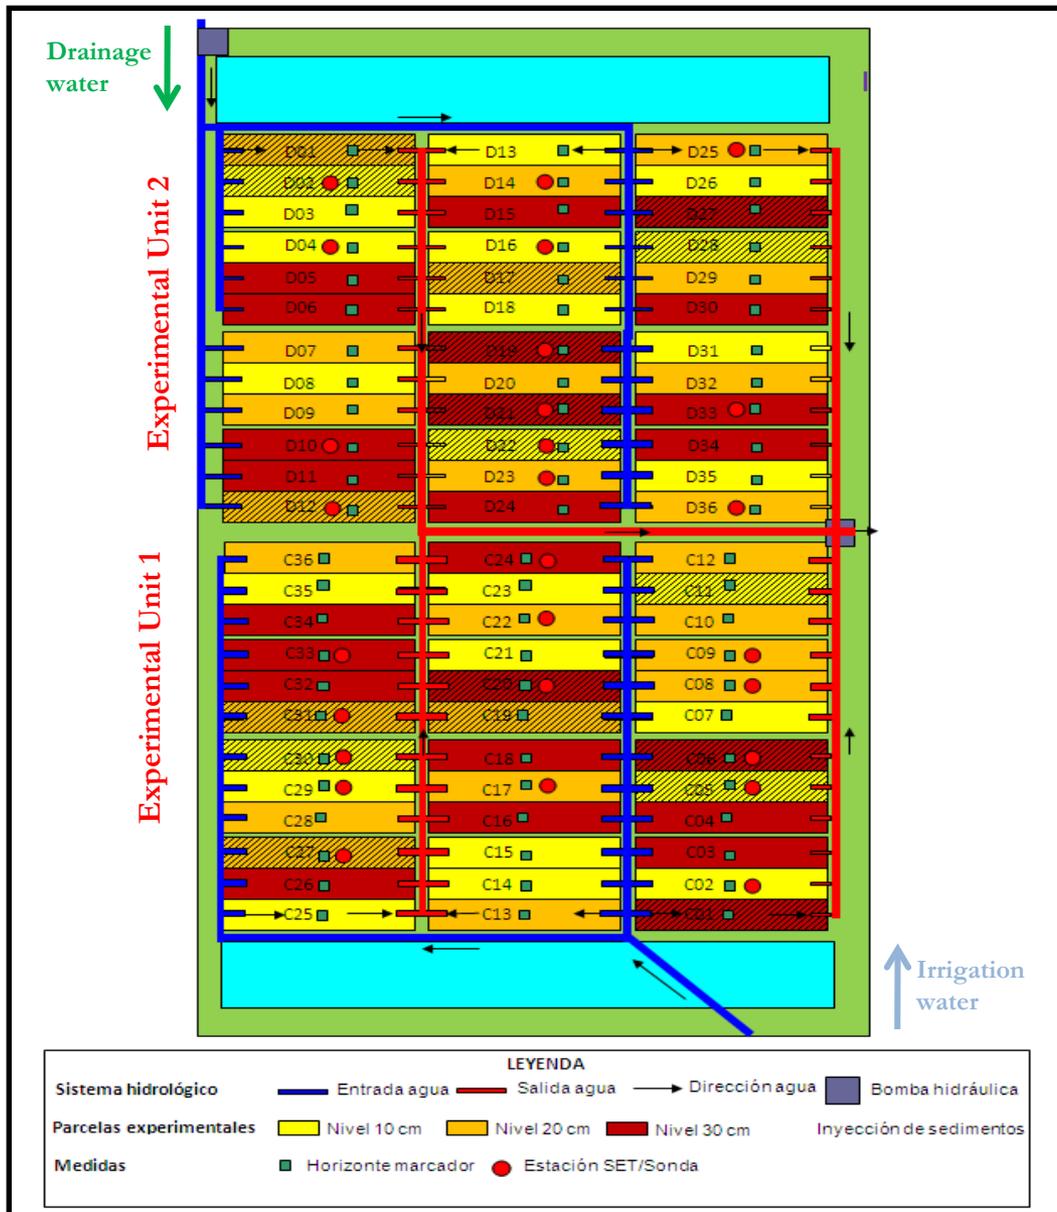

## Rice fields: the good and the bad

- Besides providing food, **Ebro Delta rice fields are outstanding in terms of ecosystem services they can potentially provide.**
- **We investigate how to optimize their ecosystem services:** increase C sequestration, reduce GHG emissions, remove nutrients and pollutants, increase soil accretion, control salinity, etc.
- However, during some periods **inputs of nutrients and pesticides affect the ecological quality of surrounding wetlands and adjacent coastal waters**, and constructed wetlands are a good tool to mitigate those impacts.
- He we show **results concerning the efficiency of experimental and real scale constructed wetlands** in the Ebro Delta in terms of several ecosystem services.

# Experimental design of small-scale wetlands

## VARIABLES:

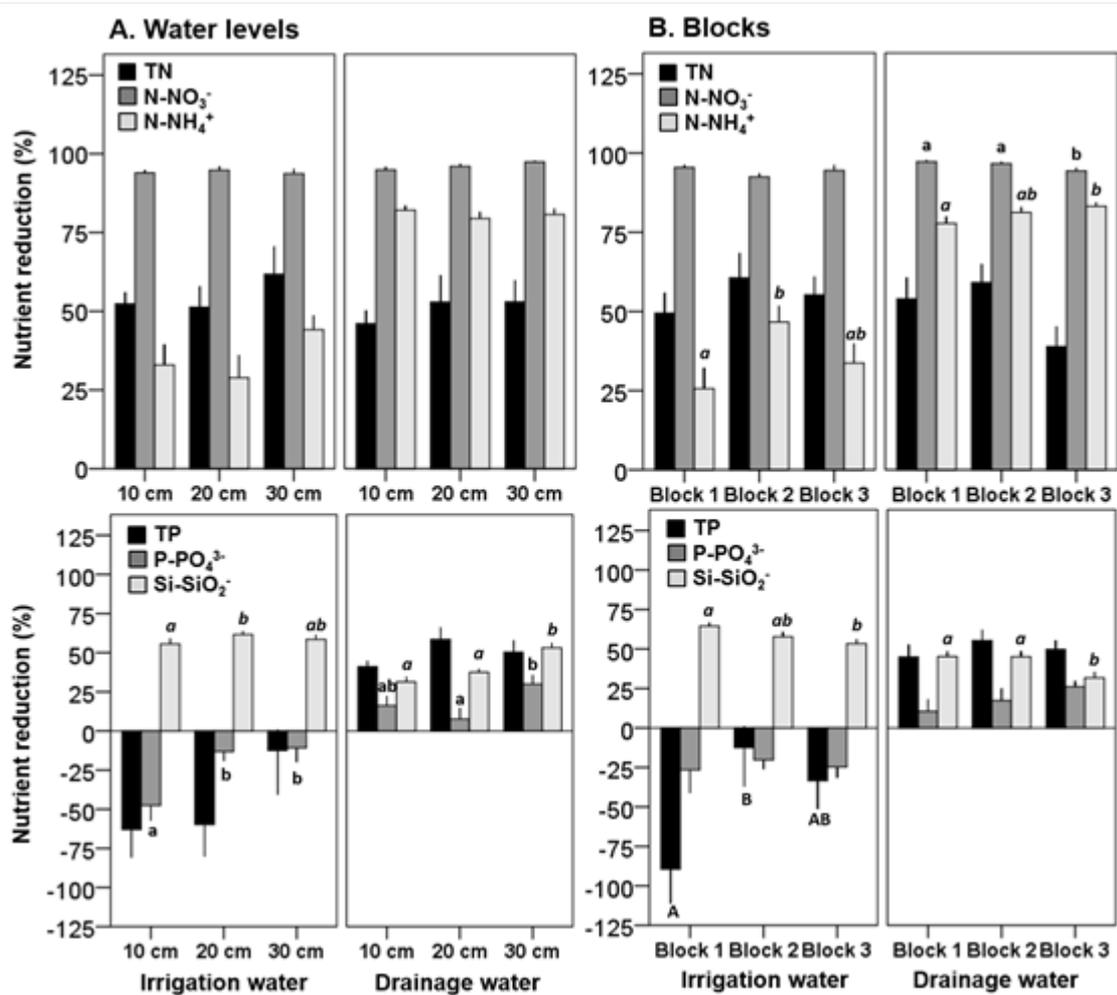

- Water input:**
    - Canal
    - Drenaje
  - Water level:** 10 cm, 20 cm, 30 cm
  - Block effect:** vegetation
- 72 x 100 m<sup>2</sup> plots in total**

# Sampling

| VARIABLE            | MEASUREMENTS  | METHOD              | FREQ.     | N° SAMPLES  |

# Nutrient removal in experimental constructed wetlands

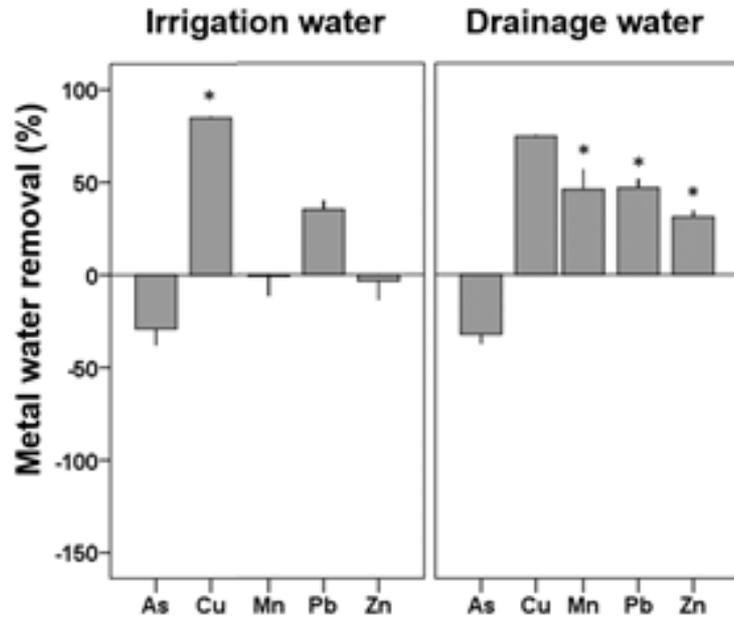

Results of the partly nested ANOVA (mean  $\pm$  SE) on seasonal nutrient reduction response among water types, water levels and blocks. When significant main effects ( $\alpha=0.05$ ) on ANOVA results among water levels and block effects were found, a Tukey pairwise test was applied within each water type treatment; significant pairwise differences ( $\alpha=0.05$ ) are denoted by different letters.

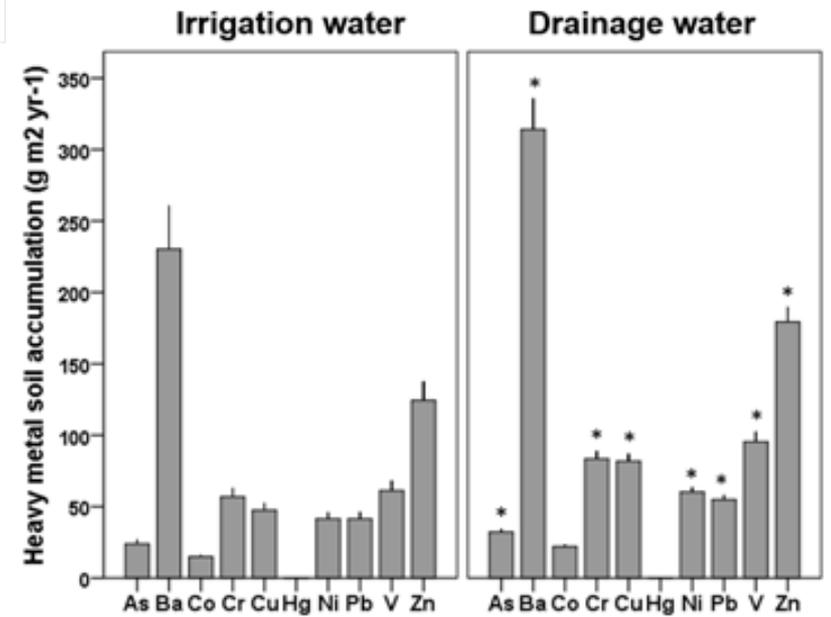

*Calvo-Cubero, J.; Ibáñez, C.; Rovira, A.; Sharpe, P.; Reyes, E. (2014). Changes in nutrient concentration and carbon accumulation in a Mediterranean restored marsh (Ebro delta, Spain). Ecological Engineering 71: 278-289.*

- Higher nutrient discharge from **rice field drainage water** caused significantly **higher seasonal N-NH<sub>4</sub><sup>+</sup> and P-PO<sub>4</sub><sup>3-</sup> reduction** ( $80.76 \pm 1.8$  and  $17.99 \pm 3.92$  % respectively).
- There was also a **seasonal export in TP and P-PO<sub>4</sub><sup>3-</sup>** ( $-45.08 \pm 13.12$  and  $-23.85 \pm 8.15$  %, respectively) in restored marshes receiving **river irrigation water**.
- Significantly **lower soil redox in restored marshes receiving river irrigation water were associated with lower N-NO<sub>3</sub><sup>-</sup> reduction and higher Si-SiO<sub>2</sub> reduction** ( $94.14 \pm 0.72$  and  $58.54 \pm 1.08$  % respectively) than those receiving drainage water.

# Metal removal in experimental constructed wetlands

PN-ANOVA results of mean ( $\pm$  SE) water metal concentration reduction (%) among water types. An asterisk indicates significant differences ( $\alpha=0.05$ ) between water types.

PN-ANOVA results of mean ( $\pm$  SE) soil metal accumulation rate ( $\text{g m}^{-2}\text{yr}^{-1}$ ) among water types. An asterisk indicates significant differences ( $\alpha=0.05$ ) between water types.

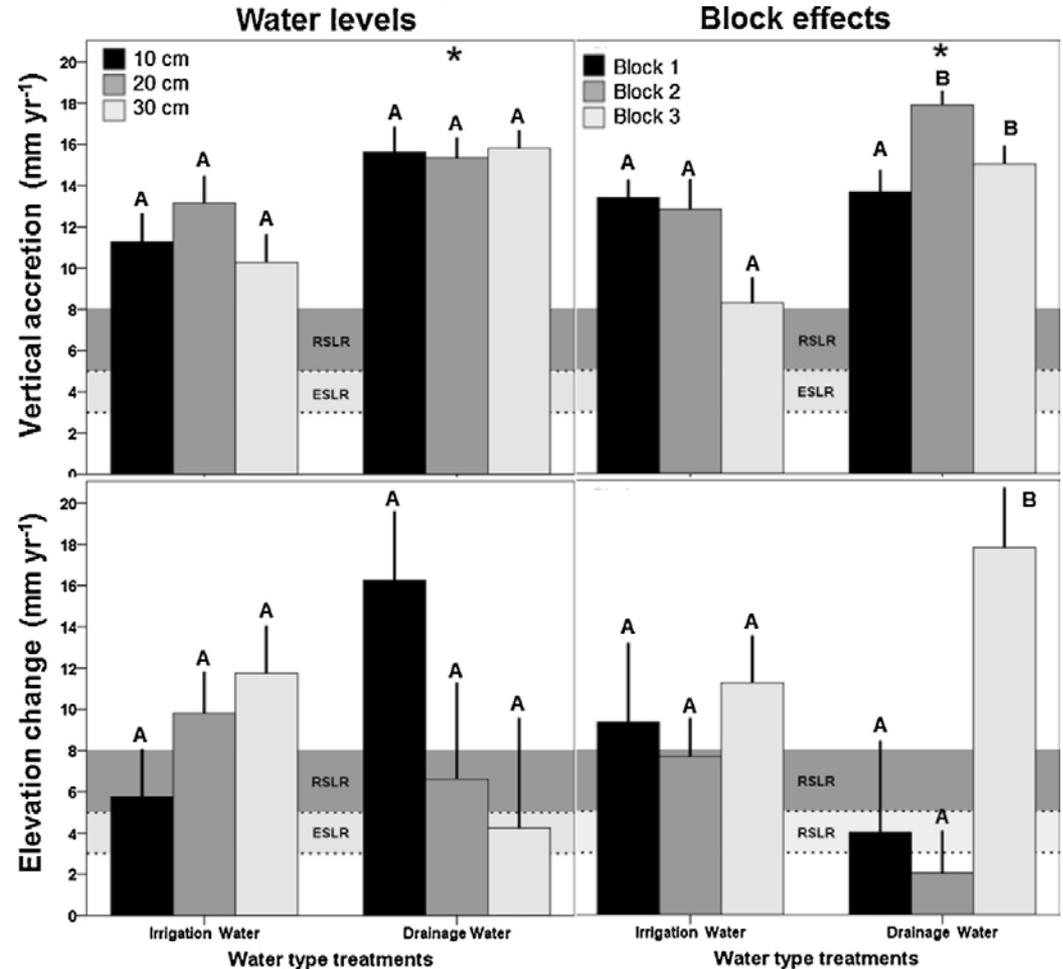

- Differences in water level regime did not cause significant differences in metal removal and accumulation in soil marshes in both water type treatments.
- Significantly higher Mn, Pb and Zn input concentration from DW caused higher mean percentage of removal (47.4, 44.1 and 23.7 %, respectively).
- Higher Cu concentration from IW also caused higher Cu reduction (85 %).
- Results suggest that wetland plants likely favored soil metal adsorption through soil oxygenation and highlight the utility of restored marshes as pollution filters in coastal wetlands

Calvo-Cubero, J., Ibáñez, C., Rovira, A., Sharpe, P. J., & Reyes, E. (2016). Changes in water and soil metals in a Mediterranean restored marsh subject to different water management schemes. *Restoration ecology*, 24(2), 235-243.

# Soil accretion & elevation change in experimental constructed wetlands

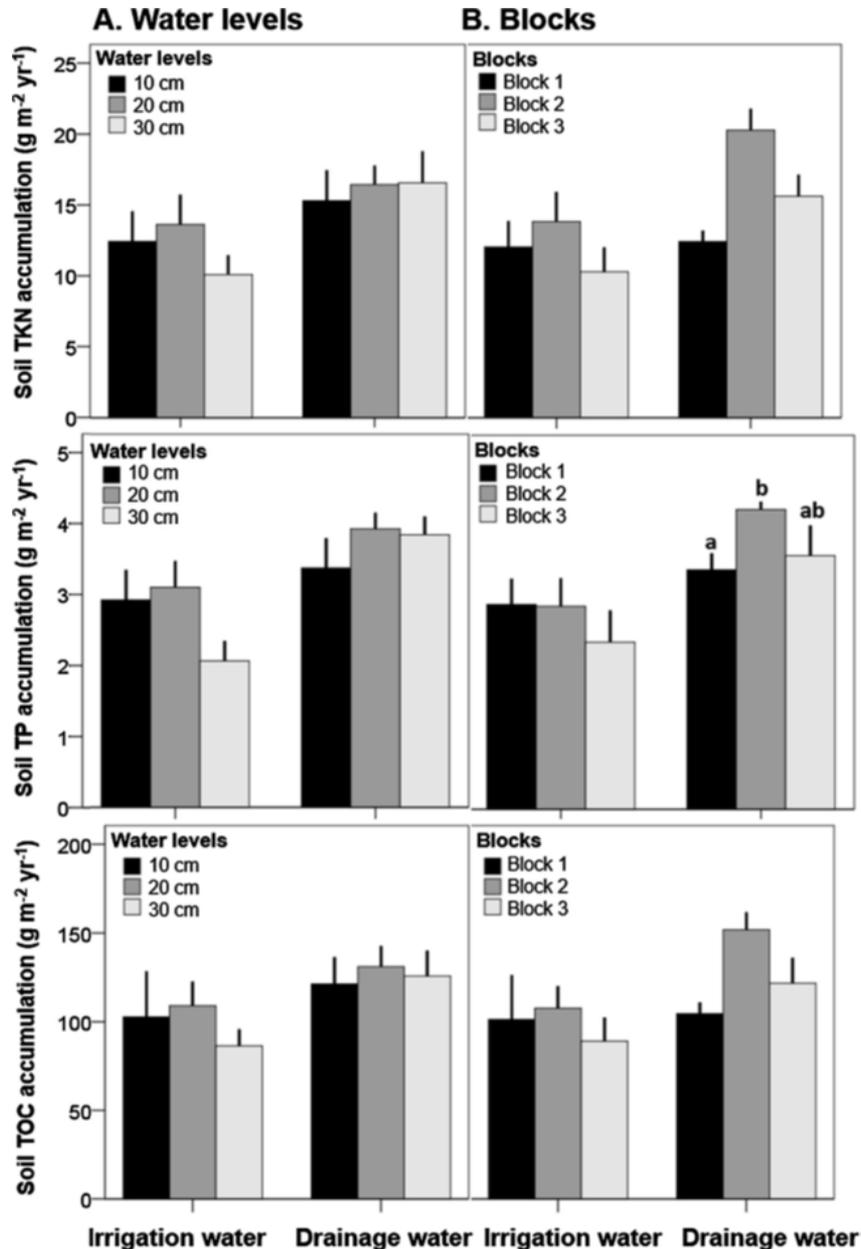

ANOVA results of mean ( $\pm$  SE) vertical accretion and elevation change response among water types, water levels and blocks. In the presence of significant differences ( $\alpha=0.05$ ), Tukey-adjusted pairwise comparisons were carried out; significant differences are denoted by different letters. The dashed line represents global (3 mm yr<sup>-1</sup>) and regional projections (5 mm yr<sup>-1</sup>) of ESLR.

**Calvo-Cubero, J., Ibáñez, C., Rovira, A., Sharpe, P. J., & Reyes, E. (2013).** Mineral versus organic contribution to vertical accretion and elevation change in restored marshes (Ebro Delta, Spain). *Ecological Engineering*, 61, 12-22.

- Vertical accretion had higher mean values in both water type treatments (11.5 and 15.5 mm yr<sup>-1</sup>) than elevation change (9.1 and 8.8 mm yr<sup>-1</sup>) (irrigation and drainage, respectively).
- Vertical accretion (but not elevation change) was significantly higher in drainage water treatment receiving greater sediment mineral input (inorganic accretion).
- Experimentally restored marshes closer to rice fields in both water type treatments had greater elevation change (11.3 and 17.8 mm yr<sup>-1</sup>) than vertical accretion (8.3 and 15.1 mm yr<sup>-1</sup>) due to higher belowground biomass (organic accretion).

# C sequestration in experimental constructed wetlands

- Higher sediment concentrations from rice field drainage water were associated with higher C accumulation rates ( $126.10 \pm 6.25 \text{ g m}^{-2}\text{y}^{-1}$ ), compared with experimental marsh units receiving river irrigation water ( $99.44 \pm 8.23 \text{ g m}^{-2}\text{y}^{-1}$ ), but differences were non-significant.

- Soil TN and TP content showed no significant differences among water types and water levels, but did show some differences among blocks.

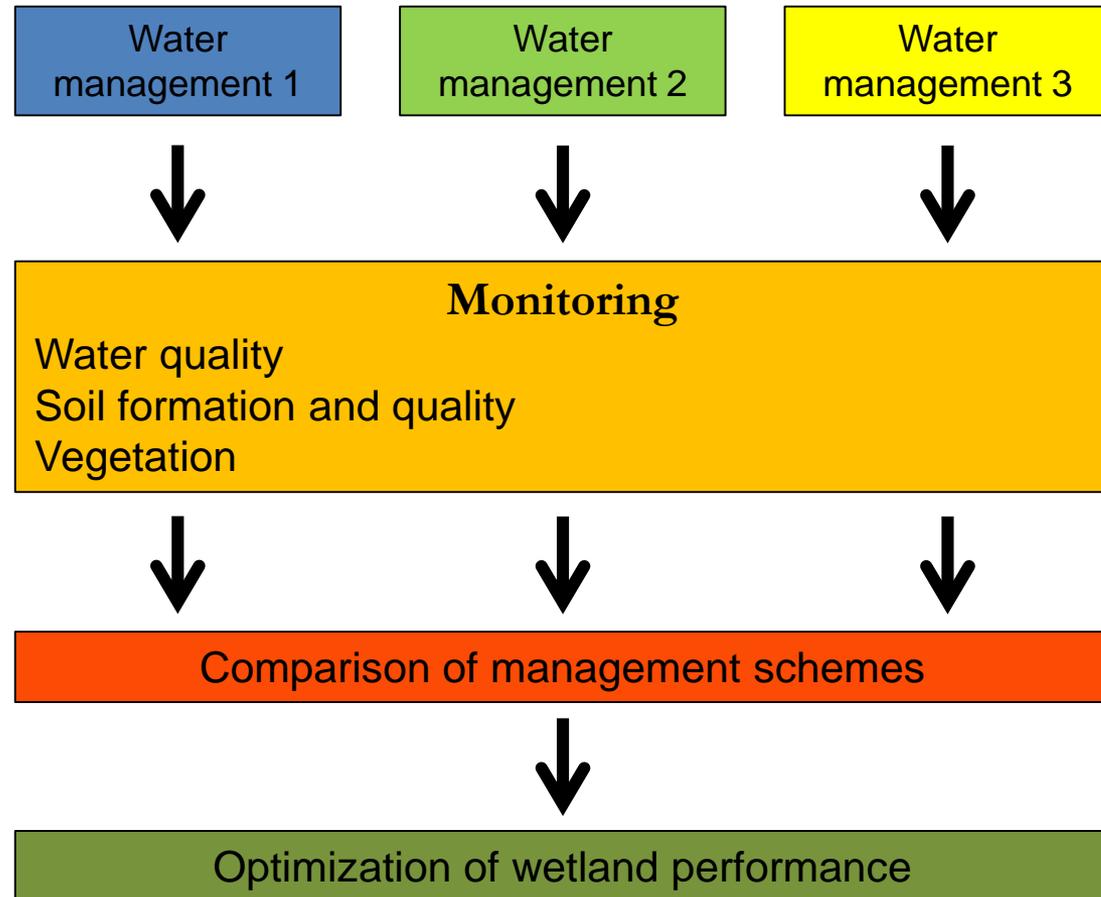

-After two years since the establishment of the restored marsh, C accumulation rates in both water type treatments showed similar values when compared to other new established created marshes ( $27\text{--}99 \text{ g m}^{-2}\text{y}^{-1}$ , e.g. Craft et al., 2003) and global estimates for freshwater marshes ( $118 \text{ g m}^{-2}\text{y}^{-1}$ ) (Mitsch et al., 2013), but half of salt marshes ( $210 \text{ g m}^{-2}\text{y}^{-1}$ ) (Chmura et al., 2003).

Calvo-Cubero, J.; Ibáñez, C.; Rovira, A.; Sharpe, P.; Reyes, E. (2014). Changes in nutrient concentration and carbon accumulation in a Mediterranean restored marsh (Ebro delta, Spain). *Ecological Engineering* 71: 278-289.

# Nutrient dynamics in real constructed wetlands

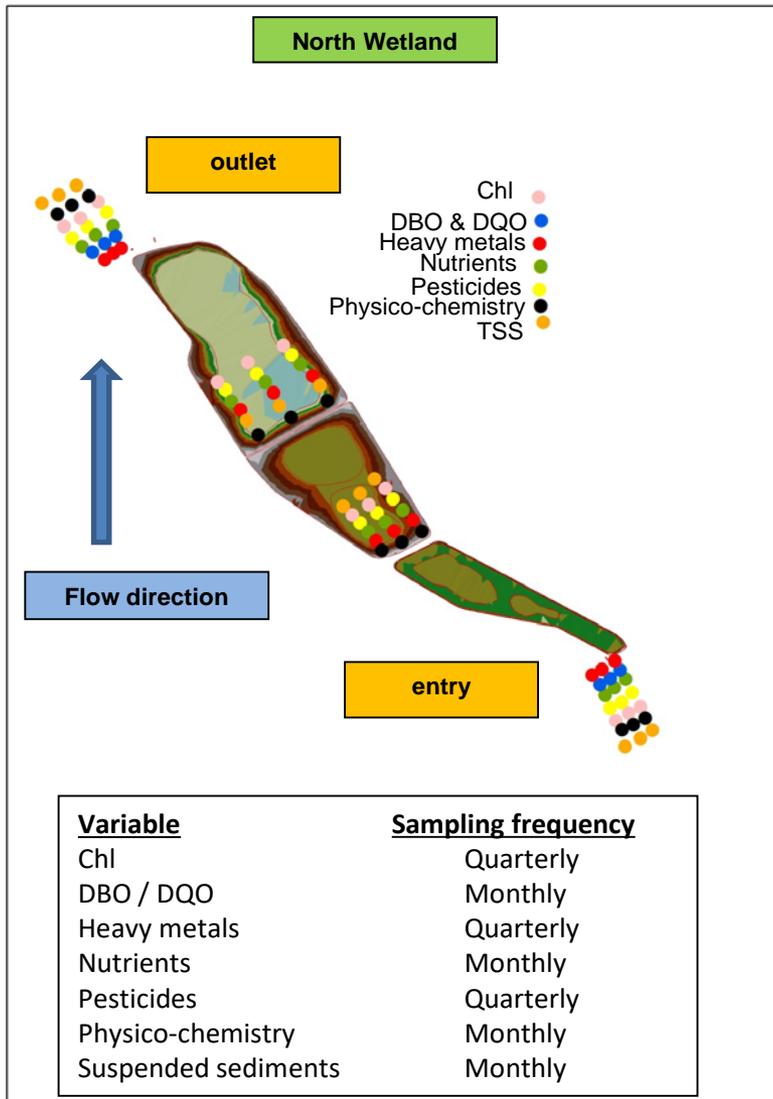

# Nutrient dynamics in real constructed wetlands

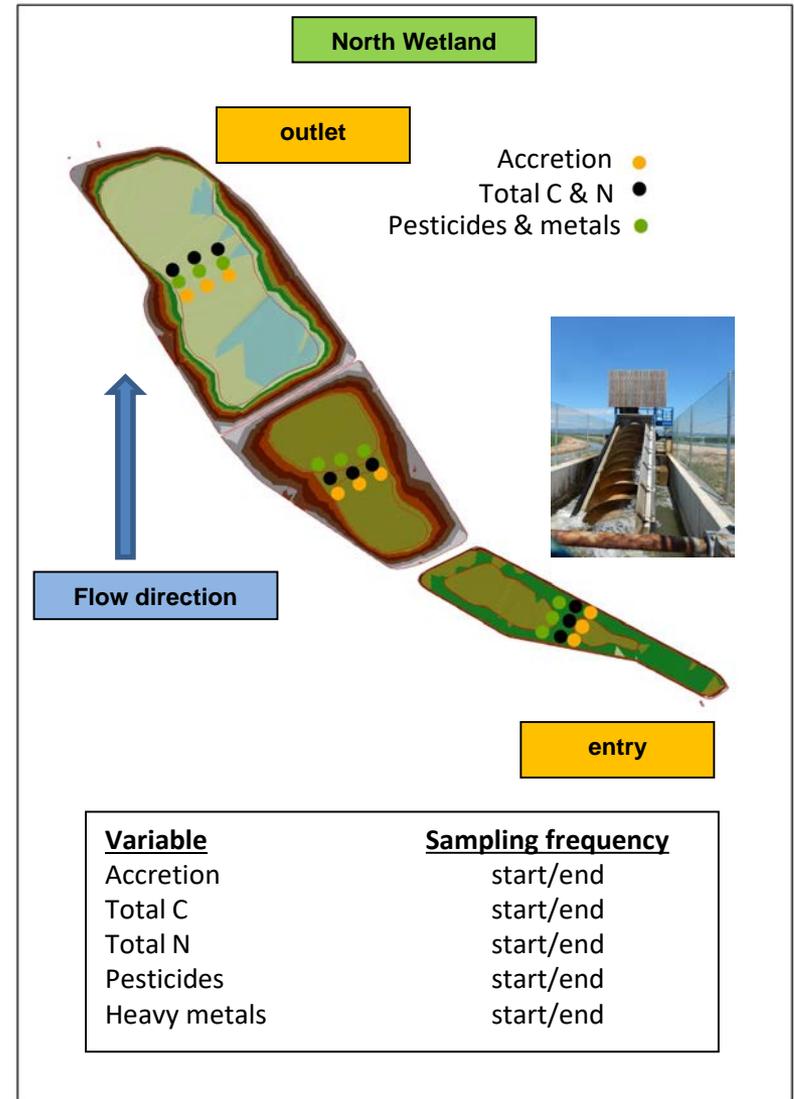

- The main goal was to **optimize the functioning of the constructed wetlands** in terms of water quality and other ecosystem services, as a function of water level and turnover.
- However, **real conditions (ecological, economic, social, etc.) made things more complicated**...the control of the hydrology was far from “perfect”.
- We decided to change the analytical methods **from a factorial approach to a multivariate one**: extract information from the complexity in space and time.

## Nutrient dynamics in real constructed wetlands (North)

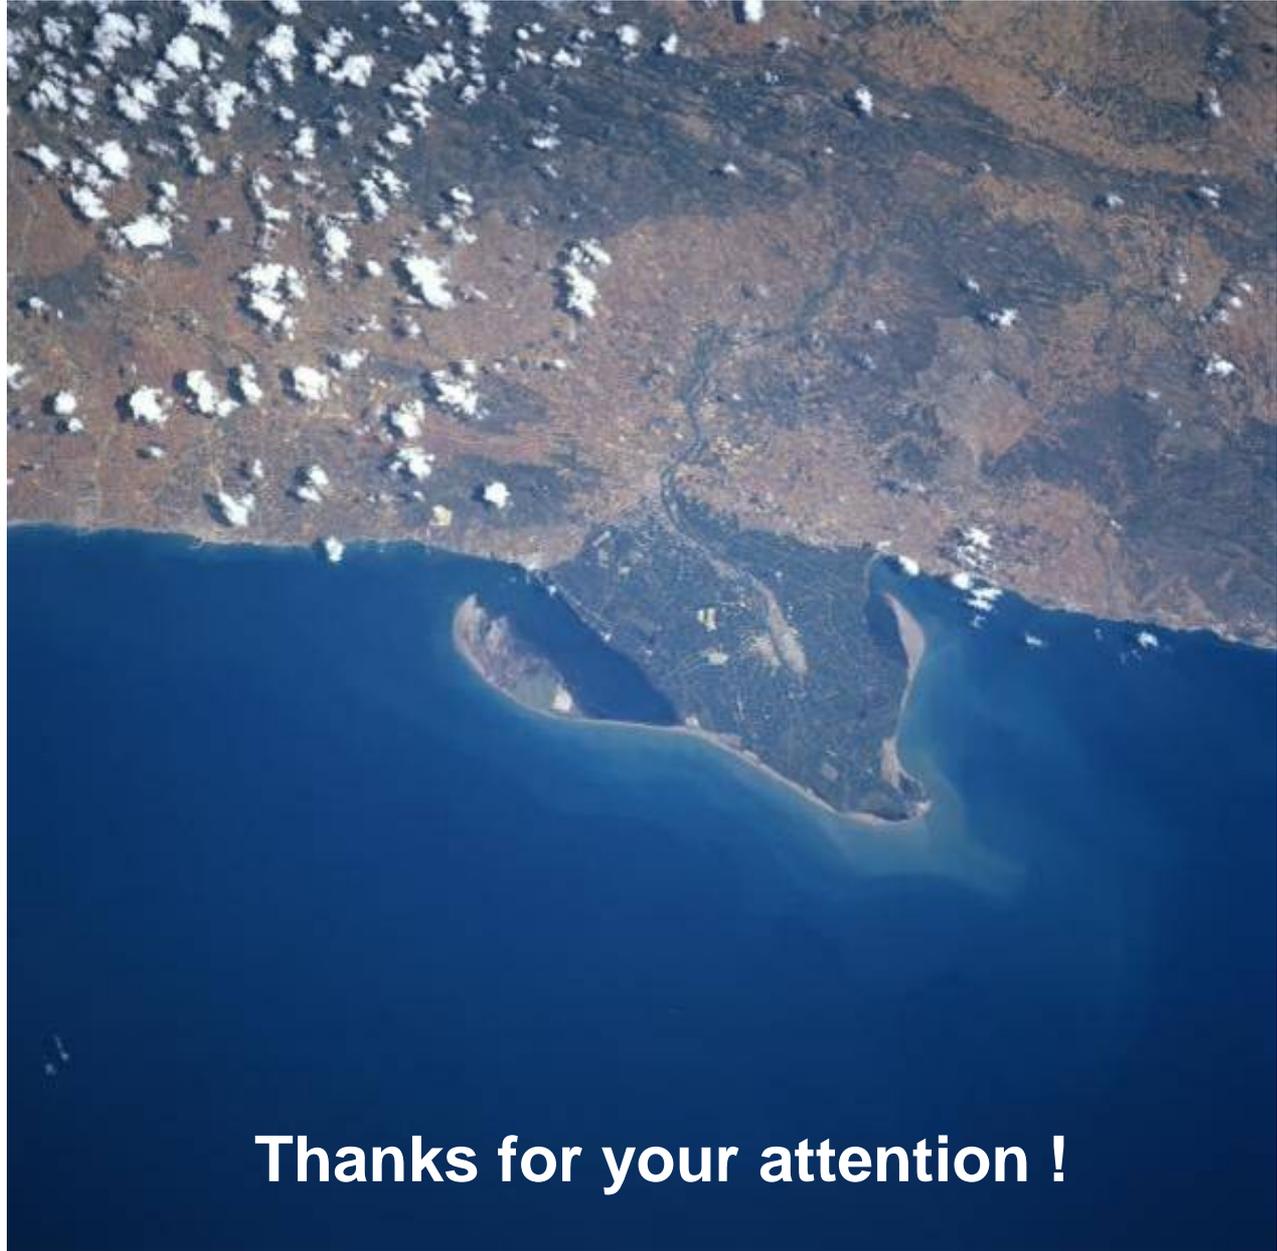

- First axis related to N and TSS and second to P and Si. Explained variance: 46%
- N, P and TSS removal efficiency related to load, but not clear for Si.
- pH (directly) and water depth (inversely) related to N and TSS removal efficiency.
- Marsh vegetation cover inversely related to P and Si removal efficiency.

# Nutrient dynamics in real constructed wetlands (North)

| Dependent variable          | Significant variables   | Adjusted R <sup>2</sup> |
|-----------------------------|---|-------------------------|
| Efficiency NO <sub>2</sub>  | Inflow concentration NO <sub>2</sub><br>Ph                            | 0.612                   |
| Efficiency NO <sub>3</sub>  | Inflow concentration NO <sub>3</sub><br>Ph                            | 0.476                   |
| Efficiency NH <sub>4</sub>  | Ph<br>Inflow concentration NH <sub>4</sub><br>Electrical Conductivity | 0.452                   |
| Efficiency PO <sub>4</sub>  | TRH<br>Inflow concentration PO <sub>4</sub>                           | 0.325                   |
| Efficiency SiO <sub>2</sub> | -   | -                       |
| Efficiency TSS              | Inflow concentration TSS  | 0.543                   |

**Results of the stepwise regression (forward) concerning removal efficiency (p<0.05).**

- As expected, **removal rates depend on load and also pH**. Silica goes its own way (?).
- **The space&time to remove N and TSS was smaller than P and Si**. Turnover (TRH) was only significant for PO<sub>4</sub> removal rate. Turnover rate was low in general (ca. 1 month).
- Complexity in terms of hydrological functioning, ecogeomorphic conditions, operational constraints, etc., prevented the initial goal to compare “standard” management schemes.
- **A multivariate approach with exhaustive data across space and time is necessary to disentangle the complexity of real scale constructed wetlands.**
- More stuff coming through.... (metals, pesticides, soil accretion, C sequestration, etc.).
- The next question is: **how to optimize the different ecosystem services?**

**Thanks for your attention !**
