The importance of structure

The importance of structure

The importance of structure

Hen and Chickens, Islamorada, Florida

“Improving estimates of coral reef construction and erosion with in situ measurements”
Kuffner *et al.* 2019

- Mean annual erosion rate of **5.5 mm per year** in the Florida Keys over 17 years

The importance of structure

Traditional rugosity metrics:

- Visually on a graded scale
- In situ measures such as 'tape-and-chain' method
- Combination of the two

Limitations:

- Observer bias
- High variation according to placement
- Non-repeatability
- Two dimensional

5 study sites: high-relief pinnacle habitat
FWC Coral Reef Evaluation & Monitoring Project (CREMP)
Collected in 2019-2020

The importance of structure

- Coral assemblages in the Dry Tortugas are shifting dramatically
- Massive reef-building corals are more susceptible to stressors vs. smaller weedier genera
- Quantifying structural footprints of susceptible corals will help to determine how reef functionality will be impacted in varying scenarios of decline

Percent cover
($\pm$ 95% CI)

Coral Percent Cover in the Dry Tortugas (CREMP)

STUDY OBJECTIVES

1. Reconstruct benthic habitat using SfM photogrammetry
2. Derive several fine-scale terrain attributes previously shown to be ecologically meaningful
3. Is there significantly distinct topographic structure between coral genera and functional groups of corals (massive vs. weedy)?

Structure-from-Motion workflow

- Imagery collected by diver swimming two passes 2 m above the substrate
- Results in between 1,000 and 1,500 images per transect with 90% overlap
- 4 ground control points (GCPs): GPS coordinates (x, y), depth (z), and 5 cm scale

4 transects per site

~160 m² per site

Structure-from-Motion workflow

Input imagery

Sparse point cloud

Dense point cloud

Solid 3D mesh

Export rasters

Terrain attributes

Slope

Maximum rate of elevational change (in degrees)

Terrain attributes

Terrain attributes

Terrain attributes

Terrain attributes

Curvature

Profile
curvature

2nd derivative of slope - indicates horizontal **concave** (-) or **convex** (+) forms

Terrain attributes

0

Profile Curvature

Summary of conclusions

MASSIVE CORALS

Exhibited highest complexity (TPI) and slope/positive profile curvature, indicative of steep topography with convex forms

Distinction between star corals and brain corals

Percent cover
($\pm$ 95% CI)

Coral Percent Cover in the Dry Tortugas (CREMP)

Summary of conclusions

WEEDY CORALS

Exhibited highest SAPA, although range in SAPA between all corals was narrow: artifact of only tracing live tissue

Porites exhibited highest complexity and positive profile curvature

- *Porites porites* is the only branching species to be included in analysis

Siderastrea & Stephanocoenia had lower slope and negative profile curvature, indicative of flat and concave form

Percent cover
($\pm$ 95% CI)

Coral Percent Cover in the Dry Tortugas (CREMP)

Summary of conclusions

Quantifying structural “contributions” of susceptible genera helps to determine how reef functionality will be impacted in varying scenarios of decline

Percent cover
($\pm$ 95% CI)

Coral Percent Cover in the Dry Tortugas (CREMP)

Significance & Future Directions

METHODOLOGY

SfM is an effective and accurate tool for cataloguing fine-scale topography – ‘topographic signatures’

Significance & Future Directions

METHODOLOGY

SfM is an effective and accurate tool for cataloguing fine-scale topography – ‘topographic signatures’

CHANGES OVER TIME

Continuation of imagery collection along CREMP transects to assess temporal changes in reef structure

Significance & Future Directions

METHODOLOGY

SfM is an effective and accurate tool for cataloguing fine-scale topography – ‘topographic signatures’

ECOLOGICAL CONTEXT

Make predictions for how changes/loss in coral structure will impact ecological processes and reef organisms

CHANGES OVER TIME

Continuation of imagery collection along CREMP transects to assess temporal changes in reef structure

Significance & Future Directions
