

SEEING THE FOREST THROUGH THE DEAD SEAGRASS

Christopher Kelble, Joan Browder,
Lindsey Visser, Charline Quenee

Outline

- Why sportfish are important? And how are they used for Everglades Restoration?
- What do they tell us about the “health” of Florida Bay
- How did they respond to the seagrass die-offs
- Chris’ hypotheses

Everglades Sport Fishery

- Generates ~US \$880 Million per annum and >6,000 jobs (Fedler et al. 2009)
- Spotted Seatrout (*C. nebulosus*) 2nd most commonly caught fish in Florida Bay
- *C. nebulosus* spend entire life history in natal Bay

Population Controls

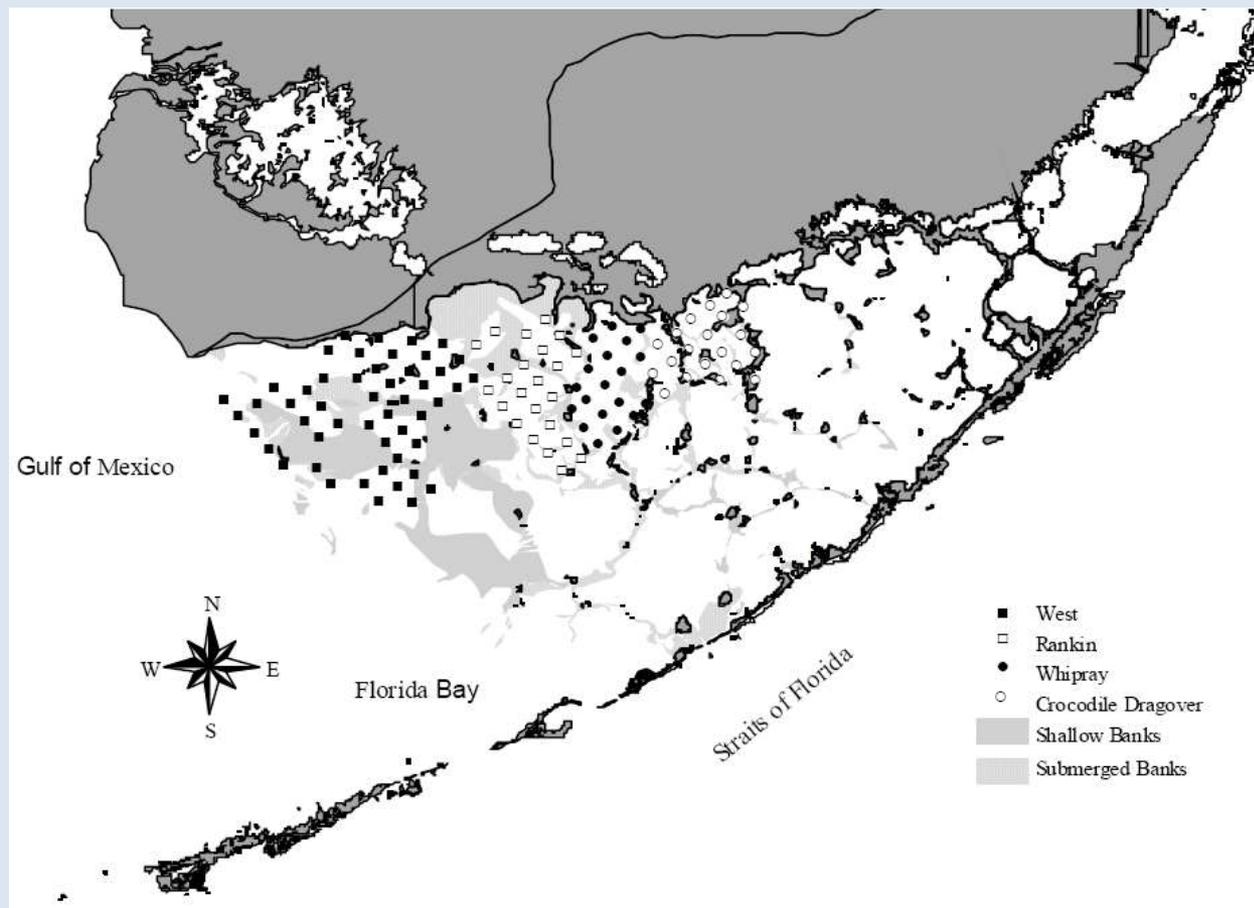

1. Physiology
2. Recruitment
3. Prey
4. Predators (and the ability to hide from them)

Methodology

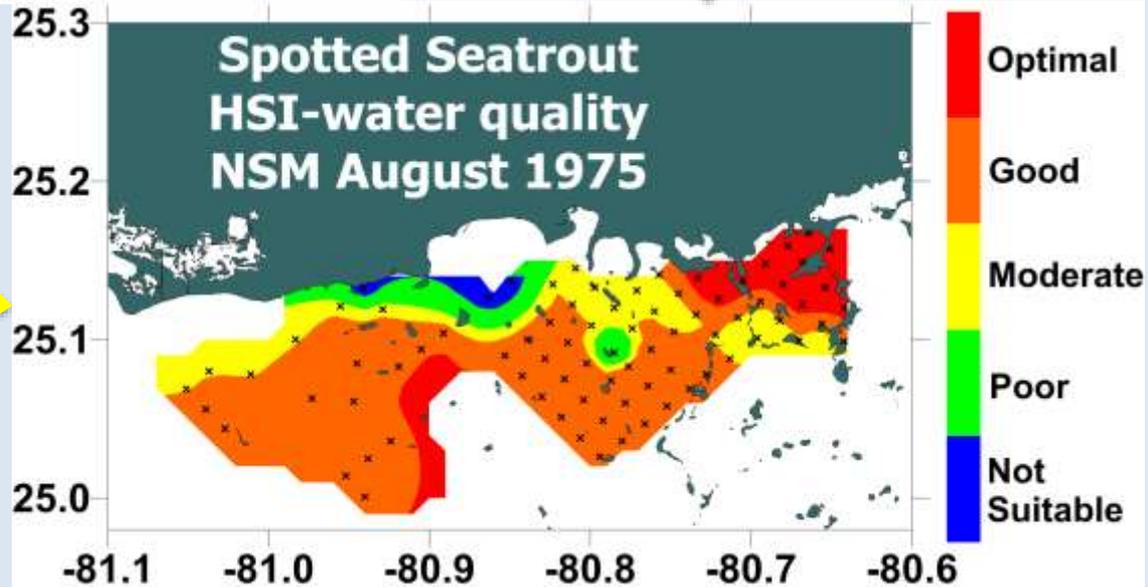

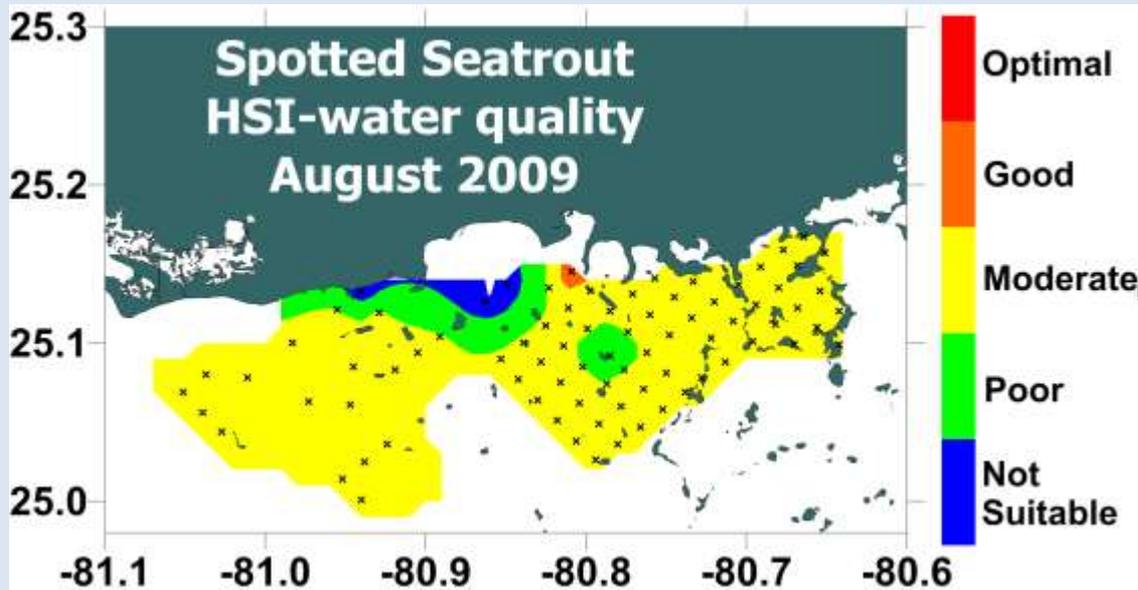

- May-Oct
- Monthly
- Otter trawls
- Seagrass, T, S
- Stratified Random Sampling
- Optimized with power analysis

Sampling: 2004-present, 1994-2001, 1984-1985

Why?

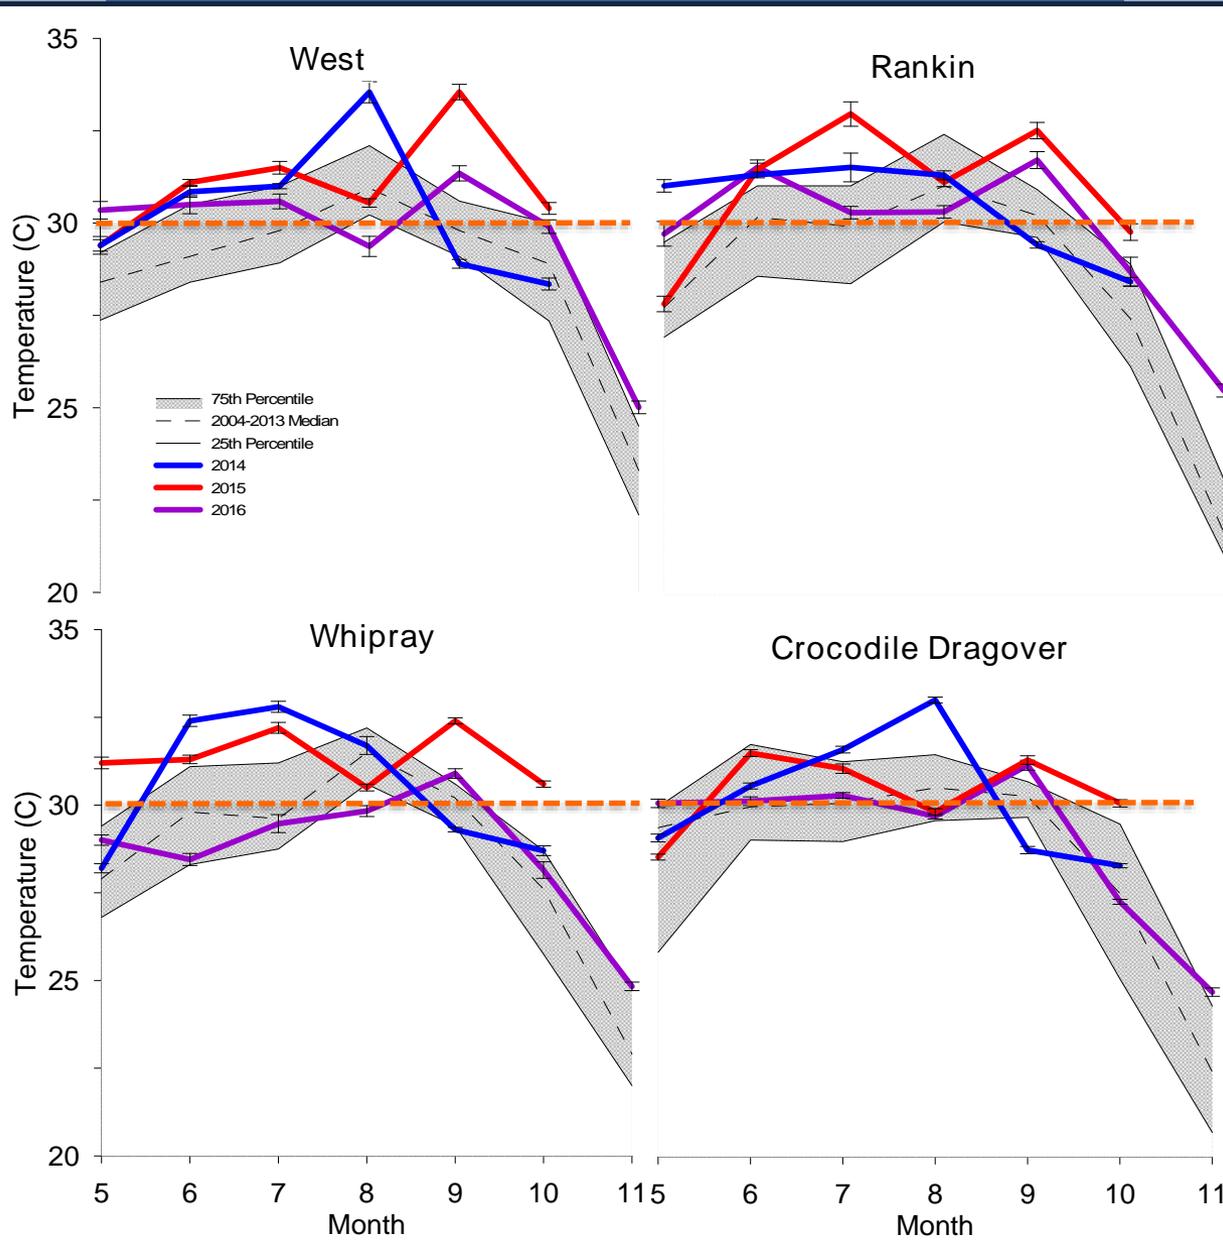

Why?

Why?

Summary

- Less seagrass habitat in Rankin and West
 - May be offset by increased turbidity
- Lower physiological stress in 2016 compared to 2014 & 2015
- Hypothesis: Increased prey in 2016
 - increased phytoplankton

Next Steps

- Apply juvenile seatrout HSI models for 2014-2016 for water quality and seagrass
 - Interactive effects & validation of models
- Compare gut contents in 2016 versus 2014-2015
- Examine abundance of prey species in 2016 versus 2014-2015
- Examine potential relationship to turbidity
- Predator abundance (Creel Survey)

Seagrass Relationship

Lower salinities and higher seagrass percent cover correspond to higher seatrout Frequency of Occurrence.
